

has a clear and concise syntax. It is based on C++, which makes it even more accessible to programmers who are familiar with C++. To simplify the language, Java has removed several perplexing and seldom-used features, such as explicit pointers and operator overloading.

In addition, Java manages memory automatically and provides an automatic garbage collector, removing unused objects automatically. This eliminates the need for manual memory management and makes it easier for programmers to focus on their code rather than worrying about memory allocation.

2. Java is a platform-independent language

When Java programs are compiled, they are converted into an intermediate level language called bytecode. This bytecode is a fundamental component of the Java platform and can run on any machine, thanks to the Java Virtual Machine (JVM) interpreter. As a result, Java allows code reusability across multiple platforms.

3. Java is an object-oriented programming language

Java is an object-oriented programming language, which utilizes the principles of OOP to simplify the creation of programs. By dividing the program into numerous objects, OOP enables data flow between functions via these objects acting as a bridge. As a result, data and functions can be easily modified to meet the specific requirements of the program.
