

comments in Dart: C# Style (///) and JavaDoc Style (/**...../). It is recommended to use “///” for doc comments as the asterisk () in JavaDoc Style makes it difficult to read the comments, especially when using a bulleted list. Doc comments are ideal for writing public APIs.

```
/// This is a documentation comment
• bool checkEven(n){
•   /// Returns true if n is even
•   if(n%2==0)
•   return true;
•   /// Returns false if n is odd
•   else
•   return false;
• }
•
• int main(){
•   int n = 43;
•   print(checkEven(n));
•   return 0;
• }
```

Output:

False

Variables in Dart

In programming, a variable is a name given to a memory location used to store data that can be accessed when needed by calling its name. There are different types of variables used to store data, depending on the type of data that needs to be stored.

To declare a variable, the syntax is:

```
type variableName;
```

To declare multiple variables of the same type, the syntax is:

```
type variable1Name, variable2Name, variable3Name, ..., variableNName;
```

The rules for writing variable names or identifiers in Dart are as follows:

1. Variable names cannot be keywords.
2. Variable names can contain both alphabets and numbers.
3. Variable names cannot contain spaces or special characters except for underscore (_) and dollar sign (\$).
4. Variable names cannot start with a number.

Note: Dart supports type-checking, meaning it checks whether the data type and the data that a variable holds are consistent.
