

In this example, the “`display.newImage`” function is used to create a new image object, which is then assigned to the “`image`” variable. The “`myImage.png`” file is located in the same directory as the Lua script.

Another useful feature of Corona SDK is its support for physics simulations. The “`physics`” library can be used to create objects that interact with each other in a realistic way. Here’s an example of how to create a ball that bounces off the walls of the screen:

```
• local physics = require("physics")
• physics.start()
•
• local ball = display.newCircle(0, 0, 20)
• ball.x = display.contentCenterX
• ball.y = display.contentCenterY
• physics.addBody(ball, { bounce = 1 })
```

In this example, the “`physics`” library is used to start a physics simulation. The “`display.newCircle`” function is used to create a new circle object, which is then assigned to the “`ball`” variable. The Lua programming language is easy to learn and use, and is very versatile. It is also quite fast and efficient, making it a great choice for mobile app development. Because it is an interpreted language, it is easy to test and debug code, and the learning curve is much shorter than that of other languages. One of the key advantages of using Corona Labs is that it has a large and active community of developers who are always willing
