

are set to automatically start up when you turn on your computer, which can slow down the boot process. To disable these programs, go to your Task Manager (right-click on your taskbar and select “Task Manager”) and click on the “Startup” tab. Disable any programs that you don’t need to start up automatically.

- **Upgrade your hardware.** If you’ve tried all of the above and your computer is still running slowly, it may be time to upgrade your hardware. Adding more RAM or upgrading to a solid-state drive (SSD) can significantly improve your computer’s performance. Consult with a professional if you’re not comfortable doing this yourself.

Issue: Your computer is running slow and programs are taking longer than usual to open.

Slow computer performance can be caused by several factors, including insufficient memory, software issues, and malware infections.

Solution:

- Check your computer’s memory usage by opening the Task Manager and reviewing the performance tab. If your computer is using more than 80% of its memory, consider upgrading to more RAM or closing unnecessary programs.
- Run a virus scan on your computer to check for malware infections. Use a trusted antivirus software to detect and remove any malware.
- Uninstall any unnecessary programs or applications that may be taking up valuable storage space on your computer.
- Check for software updates and install any available updates. This can help fix bugs and improve the performance of your computer.
- If all else fails, consider bringing your computer to a professional for diagnosis and repair. They can help identify any

underlying hardware or software issues that may be causing slow performance.

Issue: Computer is running slow and freezing frequently

Solution:

- Run a virus scan to check for any malware or viruses that may be causing the issue.
- Clear out temporary files and other unnecessary files using the Disk Cleanup utility.
- Uninstall any unused programs or applications to free up space on the hard drive.
- Disable any unnecessary startup programs that may be running in the background and slowing down the computer.
- Upgrade the RAM if the computer has less than 4GB, as this can cause slow performance.
- Run a disk check to check for any errors on the hard drive.
- Defragment the hard drive to improve performance.
- Update the device drivers and the operating system to the latest version.

Issue: The computer is overheating and shutting down abruptly.

Overheating is a common issue in computers, especially in laptops. The following steps can be taken to address the overheating issue:

- **Check for Dust:** Dust accumulation is one of the primary reasons for overheating. Dust clogs the air vents and fans, hindering the airflow and increasing the internal temperature of the computer. To resolve the issue, the computer needs to be cleaned of dust. Use a can of compressed air to blow out any dust buildup from the air vents and fans.
- **Check for Fan Functionality:** The fans inside the computer are responsible for cooling the internal components. If the fans are not working correctly, the internal temperature will rise, causing the computer to overheat. To check the functionality of the fans, boot up the computer and listen for the sound of the fans. If they are not spinning or are making unusual sounds, they need to be replaced.
- **Check for Software Issues:** Malware or unwanted programs can cause the computer to overwork the internal components, leading to overheating. Use an antivirus software to scan the computer for any malware or unwanted programs. Uninstall any unwanted programs, and update the operating system and software to the latest version.
- **Use a Cooling Pad:** A cooling pad is a device that helps cool the computer by providing additional airflow. Place the laptop on a cooling pad to help dissipate the heat generated by the internal components.

By following the above steps, the issue of overheating can be resolved, and the computer will function normally without any sudden shutdowns.
