

Mouse

Make sure the clicks are on point

A computer mouse is a peripheral input device that is used to control the movement of a cursor on a computer screen. It typically consists of a small, handheld device with one or more buttons and a scrolling wheel.

The mouse is placed on a flat surface, such as a desk or mouse pad, and moved around by the user's hand. As the mouse is moved, a ball, laser, or optical sensor inside the device detects its movement and sends signals to the computer, which then moves the cursor on the screen.

The buttons on a mouse are used to perform various actions, such as clicking on icons, selecting text, or opening menus. The scrolling wheel is used to navigate through long documents or web pages by scrolling up and down.

Modern computer mice may include additional features, such as programmable buttons, customizable sensitivity settings, and wireless connectivity. Some specialized mice are

designed for gaming or graphic design, with extra buttons and higher sensitivity for precise movements.

Overall, the computer mouse is an essential tool for navigating and interacting with a computer and has become a ubiquitous part of computing since its introduction in the 1980s.

What are the different components of computer mice?

Computer mice are made up of several components, each with its own unique function. Here are the different components of a computer mouse:

- 1. Housing:** The housing of the mouse is the outer shell that holds all the internal components together.
- 2. Buttons:** The buttons on a mouse are used to perform various actions, such as selecting text or clicking on icons. Most mice have two buttons, a left and a right button, while others may have additional buttons for specific functions.
