

even overclock your system for the best performance. Our professional advice is here to help you if you're having difficulties choosing the best benchmarking programme for your PC.

1. HWMonitor

Instead of marketing itself as a benchmarking tool, HWMonitor positions itself as a hardware monitoring solution. But gamers use it more than any other group of tools. The software has a straightforward user interface that shows voltage, power use, temperature, clock speeds, and fan speeds for your machine.

If you're attempting to figure out why your desktop is heating up, HWMonitor is very helpful. One of the most frequent causes of repeated shutdowns is high temperatures, and HWMonitor may assist you in finding the problem by monitoring the temperatures of your CPU and GPU under various conditions and loads.

The most used and cost-free version of HWMonitor is the classic version. However, there is also a more potent paid version that has an enhanced user interface and can monitor devices remotely. Up to 20 remote connections are supported, and two years of upgrades are free.

2. 3DMark

When it comes to testing the gaming performance of your PC, 3DMark is one of the best benchmarking programmes. The package includes a number of gaming benchmarks with names you're probably familiar with, like Port Royal (ray tracing), Time Spy (DX12), and 3DMark Fire Strike (an earlier DX11 test).

All of these tests will provide you with a score and allow you to compare it to other PCs using similar (or different) hardware components. This will allow you to see how well you stack up against other 3DMark users, of which there are many, and determine whether your system needs to be tuned. Additionally, 3DMark also provides you with some estimated frame rate performance numbers for a number of well-known games.

Of course, these benchmarks will be helpful for anyone considering overclocking their system, and 3DMark also enables you to stress test the stability of your overclock by repeatedly performing a looping benchmark.

For a free trial to test out 3DMark's benchmarking features, download the demo from Steam.

3. User Benchmark

To assist you in choosing the top hardware for your requirements, UserBenchmark provides a free all-in-one suite that can be used to benchmark your CPU, GPU, SSD, HDD, RAM, and even USB. A group of developers created the programme as a side project rather than as a service for a company.

It not only generates a tonne of data and the hardware's net score, but it also makes recommendations on how to boost performance. You are able to identify the particular area of your desktop where performance is lacking since every piece of hardware is given a specific grade based on how well it performed in the tests.

However, users should be aware that there are numerous controversies surrounding this software. The team has received harsh criticism for its frequent personal assaults on tech journalists, and the benchmarks themselves have been accused of manipulating the results to favour one hardware manufacturer over another.

4. Cinebench

CineBench includes everything you need for a thorough assessment of your CPU and GPU performance. The free app rates your rig's performance using picture rendering jobs and is accessible on the majority of systems.

Using tests that produce 4D images, Cinebench rates the speed of the CPU and OpenGL. For high-end systems that go beyond the capabilities of standard benchmarking tools, it is very helpful. It produces reports for those working in the content development sector that are useful and founded on actual performance.

The finest feature of Cinebench's thorough 4D rendering test is that it utilises every core of your CPU, pushing it to the hardware's absolute limits. When attempting to create a high-end computer and seeking advice on which components to utilise, the product is quite helpful.

5. Geekbench

One of the top Windows benchmarking programmes, Geekbench is also accessible on Android, iOS, macOS, and Linux.

It performs several tests on your CPU, some of which make use of more recent software like augmented reality and machine learning. You may use a variety of GPU APIs with Geekbench, including OpenCL, CUDA, Metal, and even Vulkan. The benchmarking tool also features the distinctive capability of cross-platform benchmark comparisons, which you can use to assess the performance of your Windows PC against a Mac or your Apple iPhone against an Android smartphone.

Linux, macOS, or Windows all support Geekbench. You can purchase a licence that will enable one user to use the programme
