

mance tests can reveal areas where your app lags or consumes too much memory.

Interpreting test results is crucial to understand the potential improvements needed for your app. Here's how you can do it:

- **Analyze the test logs:** Test logs provide detailed information about what happened during the tests. Look for any errors or warnings that could indicate potential issues.
- **Use monitoring tools:** Tools like Android Profiler can help monitor CPU, memory, and network usage during testing. High usage could indicate potential performance issues.
- **Feedback from usability testing:** This can provide insight into how users interact with your app and potential areas for improvement.
- **Test coverage reports:** These indicate which parts of your code were executed during testing. Areas with low coverage might need additional tests.

Remember, testing is an iterative process. As you make changes to improve your app, re-run the tests to ensure that your updates work as expected and don't introduce new issues. By following these steps, you can ensure your app offers a great user experience on foldable devices.

Common issues and troubleshooting

When developing applications for foldable screens, developers can encounter a variety of issues. This section will discuss common problems faced during foldable screen testing and provide step-by-step solutions to these issues.

Application doesn't properly span across Screens

To resolve this, developers need to ensure that their application supports resizable layouts. This can be done by setting the `android:resizeableActivity` attribute in the manifest file to `true`. Also, make sure to handle configuration changes correctly in your activities. By default, Android restarts your activity on configuration changes, but you can specify your activity to handle these changes using the `android:configChanges` attribute.

Incorrect app orientation

To tackle this problem, make use of the Android Jetpack WindowManager library. This library helps in determining the current device state, including its posture and orientation. Developers can use this information to adjust the app's layout and orientation accordingly.

Inappropriate UI scaling

Solution: To address this issue, developers should use flexible layouts and dynamic sizing for UI elements. Avoid using fixed pixel sizes for your UI components. Instead, use "wrap_content", "match_parent", or weighted dimensions in a `LinearLayout` to allow UI elements to adjust their sizes based on the available space.

Difficulty in Testing

Solution: Use the Android Emulator, which provides support for foldable devices starting from version 30.0.6. You can use it to emulate different foldable device configurations and test how your application behaves on them.

Testing on real devices

Testing apps on actual foldable devices can be challenging due to their cost and limited availability. Developers can use Android Emulator, which includes foldables support with a virtual hinge sensor and 3D view, for testing their apps. The emulator allows developers to test how their apps function in different postures and spans.

FAQs about testing on foldable screens

As foldable devices continue to gain traction in the market, it's important to understand how to effectively test apps on these new form factors. Here are some frequently asked questions about testing apps on foldable screens.

1. What is unique about testing on foldable screens?

Testing on foldable screens is different from testing on traditional mobile devices due to the dynamic nature of the display. Foldable devices can transition between multiple postures and configurations, presenting unique challenges for app compat-
