

Mouse & Keyboard

These rodents run akdjsakljd... WILD!

MOUSE

Acceleration

Sensor acceleration refers to the increase in cursor movement speed relative to the speed of the mouse movement. Acceleration is undesirable in high-precision gaming, where raw input is preferred. Many modern mice, particularly high-end gaming models, feature zero acceleration sensors for linear, unaltered tracking essential for pro-level gaming precision.

Angle Snapping

Angle snapping (or prediction) adjusts the movement of the cursor to smooth out diagonal or straight lines. This feature is useful in applications like photo editing or CAD, but detrimental in gaming, where raw, unfiltered input is required for precise aiming. Enthusiast gaming mice often have the option to disable angle snapping entirely.

Claw Grip

Claw grip users hold the mouse with their palm hovering slightly above the back, while fingertips control most movements. Mice optimized for claw grip often feature compact bodies with high arches. This grip style is favored in RTS and FPS games for fast, reactive movements, requiring lightweight and highly responsive mice.

DPI (Dots Per Inch)

DPI defines the physical resolution of the mouse sensor, determining how many pixels the cursor moves for each inch of mouse movement. Advanced gaming mice can feature DPI ranges from 200 to 20,000+, useful for both ultra-fast flick shots in FPS games and pixel-perfect accuracy in graphic design or CAD software. Custom DPI profiles allow rapid switching between sensitivity settings.
