

Gaming Using A PPU Vs On A Regular System

Let's take a theoretical game scene of a box about to explode. The scene also contains a building and a person fleeing the frame.

All this data is passed on from the game engine to the CPU for processing

How Current Games And Systems Compute And Render A Scene

Currently, the CPU keeps all data that requires physics processing and AI processing. Once the CPU is done with these, it only passes all the graphics computations to the graphics card (aka the GPU), which then renders the new position of the object and then outputs the final image or frame

The GPU takes all the graphics data and renders the scene. However, it is often bottlenecked by a comparatively slower CPU, mainly due to the load placed on the CPU because of the physics and AI calculations

The end-result is a scene that has unrealistic explosions and physics. We cannot expect any more, because CPUs, by design, need to be more general purpose, unlike a GPU, which is built solely to process graphics
