

Filter Freaks Rejoice!

One of the best ways to pass time in Photoshop—especially when you're short of ideas—is to apply random filters to your image, and hope that one of them or a combination will catch your fancy. For such creative wanderings, CS3 brings you Smart Filters. Once you convert your layer into a Smart Object, every filter you apply to it becomes like a layer effect—they will always be available for tweaking, you can reorder them to see how the combinations look, and you can turn off filters without bothering with undos and history states. The best part is that your original image remains untouched, so you can experiment with ridiculous ease. Even changing the Blending Mode of a filter—something that was available only immediately after it was applied—is now an option you can exercise at your whim.

Go crazy with your filter experiments with Smart Filters

Send In The Clones

Even the Clone Stamp tool goes one step ahead in CS3. Hold down [Shift] + [Alt], and click and drag to see a preview of your cloning. You can also select five different clone sources, which can even be from different documents.

Zoomify!

If you've got a really high-resolution image (a few MB, even) and you want to put it up on your Web site, well, you can't. Not without your visitors abusing you, anyway. Photoshop CS3 lets you export your image using the Zoomify plugin (www.zoomify.com), which creates a SWF file of your image. You can zoom in and out of it as much as you want, and Zoomify will render only the part you're looking at—just like in Google Earth or WikiMapia, with all the convenience.

Zoomify large images for a Google Earth-like effect

Lining Up Perfectly

With all those complex mathematical algorithms at their disposal, the Photoshop team has given us some incredible features for image

correction—one of these is the Auto Align Layers feature; even after plenty of uses, we still can't get enough of it. You need to try it out to believe it!

Try this: get your digital camera out and take three photos of your surroundings to create a panorama. Load all these photos into Photoshop, create a new image that's three times the width of a single photograph, and drag each of these photos as layers on to this new image. Use the Move Tool ([V]) to drag the layers around so they roughly line up, with a little bit overlapping. Select all the Layers by [Shift]-clicking them all, and go to **Edit > Auto-align Layers**. Select Auto and click OK. In a few seconds, your panorama's images will be perfectly lined up!

This is also a handy feature if you've taken two group photos, and each of them has a different person with his or her eyes shut. Auto-align the two, and with some judicious masking, you're on your way to the perfect photo.

To compensate for differences in colour tone and brightness, select all the layers again and go to **Edit > Auto Blend Layers**. Photoshop will automatically create masks for each layer, making the overall image look perfectly balanced in tone.

Going 3D

Photoshop Extended also imports 3D objects as layers, and you can slap on and edit textures right there—no more switching between Photoshop and your 3D program. Its features are rudimentary,

Bring 3D objects into Photoshop Extended

and Adobe insists that they aren't looking to break into the 3D market. Yet.

You can apply effects to these 3D layers just like regular layers, choose from a few preset lighting schemes, and apply rendering schemes that can make them look like line drawings or cartoons as well. Like we said before, this isn't very advanced, and doesn't purport to be. If you've got basic 3D models

From botched to beautiful—even this really badly-shot panorama gets aligned perfectly—with just one click! All right, two
