Feature

The web that we know is probably just the tip of the iceberg

from search engines for reasons of privacy and security. It is estimated by researchers that the Deep Web is so large that that less than 1 percent is accessible using traditional search engines since the content is stored in file formats that search engines cannot generally deal with, or can be accessed only by dynamic database queries.

Darknets, on the other hand, are specific private niches in the Deep Web that are intended to for access by trusted users. They usually require highly specialized software or tools that enable access, decode the encrypted formats, and ensure user anonymity.

Getting Inside the Darknet

Making your way into the Darknet is virtually impossible, unless you have the right tools and use the proper techniques. But once you have them, you can use many directory sites and wikis that have been created to keep track of hidden services. For instance, to access Onionland, you need to install special software, and take some safety precautions.

Once you access Onionland, you will see that it looks much like a directory listing. Hidden services turn up and vanish, often within days—and new entries crop up periodically. And it's not uncommon for the directory itself to shift URLs so that for tracking the locations, you will have to rely on Onionland itself.

Most of the directory entries you will find in Onionland make it amply clear what lies beneath. For this is the market place for weapons dealers, credit-card scammers, document and currency

GETTING INTO THE DARKNET

To access the Darknet you need special software and services. Here are some you can use:

TOR Browser

Initially developed by the US Navy as a global network of servers, TOR (short

for The Onion Router) helps you browse the internet without revealing your identity. The browser keeps switching your traffic through a relay network so that it's hard to pin down your location.

I2P Browser

Allowing you to set up peer-to-peer connection in anonymous mode, the I2P

is promoted as an alternative to TOR. It employs P2P software called the I2P layer, and this browser is meant for communicating secrets.

TailsOS

The Amnesic Incognito Live System (Tails) is

a Linux distribution and a TOR operating system that aims to provide more stringent user anonymity. Tails can be booted from a

USB drive, or a DVD, and does not leave any traces on your machine.

Orbot

A tool for Android smartphones that provides anonymity

routing traffic from the web browser through the TOR network.

Tox

Tox is a free and open-source, peer-to-peer, encrypted instant messaging and video calling software. Using Tox

you can message friends, join chat rooms, voice and video chat, and send each other files in a secure manner. All traffic over Tox is encrypted end-to-end.

IprediaOS

Another OS based on the Linux platform, Ipredia

offers a secure environment for users who want to use the Net anonymously. The traffic is automatically encrypted, and the OS provides a wide variety of applications for chatting, peer-to-peer communications, mail and file transfers.

A SANER SIDE OF DARKNET

In an increasingly connected world, privacy is becoming a major concern. Virtually all content that you create or share online is amenable to the prying eyes of ad networks, government organizations, and spy agencies. Needless to say, this scenario makes many web-users uncomfortable. Indeed, there are many who are seeking an alternative version of the Internet that is inaccessible to scanners. And the curious part is that these users do not want a private version of the Net for nefarious or illegal activities.

Hyperboria, the brain-child of programmer Caleb James, is is a

highly-encrypted network of people connected to each other in a peer-to-peer mode. The cryptographic technology has been designed with the assistance of several mathematicians, and claimed to be virtually unbreakable. But the catch is that you need an existing Hyperboria user to connect to—limiting the spread of the technology.

But that's not to say that Hyperboria isn't a happening place. Aside from The Twitter like Social-node, Hyperboria is also rich with such things as Uppit—a Reddit powered voting/sharing service.
