Intelligent life confirmed

Declassified report of the Narrowband Radio Signal received by the Big Ear Telescope on August 15 1977

Sandhya Ramesh
readersletters@dgit.in

On August 15, 1977 a 72 second long narrowband signal was intercepted by Jerry R. Ehman at the now defunct Big Ear at Ohio State University. This signal was never detected again despite constant attempts to search for such a broadcast. While all known attempts to decode that transmission were reported to have failed, recently declassified NSA documents have revealed that a translation was indeed achieved. The transmission appears to have been a report by an intelligent civilization about the habitability of our solar system.

Below is the translated report, verbatim:
Brief Report of Habitable Worlds in the Stellar System of the Sun and Earth

Since the destruction of our forward outpost in the Quarak zone of the binary

star system Kortan (closest translation: Tau-Sagittarii) the search for another habitable planet has intensified here on Morkan (translation: unknown). We have found a relatively new star system in the outer arm of stable zone of the spiral system of Chronor (translation: the Milky Way galaxy). Morkanian astronomers have dubbed this system Sol (translation: Sun) and the third planet, GS03 (translation: Earth) is of particular interest to us.

Earth had always been of major interest to scientists here at Supon Institute of Planetary Sciences (SIPS) on Morkan. We first stumbled across Earth nearly 23 years ago and having obtained a Level Five — the maximum rating — on the Foundation Habitability Meter, we focussed all our energies on obtaining funding to study and make contact with Earth. We now work on the extensive study of planet Earth and

the possibility of other habitable worlds in their stellar system: the rocky planet GS04.01 (translation: Mars) and three natural satellites of other planets coded GS05.04 (translation: Europa), GS06.13 (translation: Enceladus), GS06.06 (translation: Titan).

The following is a report of the study of Earth, how it obtained its record Habitability Meter Level, and the habitability readings of four other bodies in the system.

GS03 (Earth)

Earth captured our attention first when we noticed its transit period across its host star (called Sun). Its orbit took approximately 365 cycles (translation: days), uncannily similar to our own 385 days. We were also able to deduce that its mass was nearly equal to ours as well, but the gravity was much higher. Earth also has a unique natural satellite (called Moon)
