

Lenovo incurs loss

Lenovo reported a net loss of \$714 million in Q2 2015. Apparently this was better than what was expected: <http://dgit.in/LenovoLoss>

'Smarter' Watches

Cellular connectivity is all set to be featured in Android Wear says Google. Read here: <http://dgit.in/SWcellulr>

that formed through a giant impact and remained close to the planet, but is in a slow orbital decay. Extensive study of the Earth's atmosphere from our Orbital Telescope showed that Earth had nearly identical atmospheric components as that of our home planet Morkan. Carbon, hydrogen, oxygen, and helium are the most abundant gases in this universe; and it was thus argued that there was a higher probability to find carbon-based life than any other kind. Keeping in line with this mission, we used four main characteristics of carbon life forms to study Earth.

The Fellot Band (translation: Goldilocks Zone): Apart from the fact that Earth is rocky, it was a major find for us that the Earth sits in what is called the habitable zone or the Goldilocks zone — not too hot, not too cold, just right. It's star is the primary source of energy and would sustain everything from the weather to the water cycle to energy for life. Life forms on Earth would potentially be able to suitably harness Sun's energy naturally for sustenance, while protecting themselves from too much heat. The ideal temperature also supports liquid water on the surface.

Atmospheric Gases: Earth was the first body to show positive results for scans of all three major gases that constitute biosignatures — oxygen, methane, ozone. Oxygen on Earth is produced and sustained by plants alone. Methane is an abundant by-product of the biome, especially of the domestic cattle. Ozone in Earth's atmosphere is produced by molecular oxygen combining with atomic oxygen using energy from sunlight or lightning. In our astrobiological quest, we had quite abandoned the idea of looking for each of these gases individually as they do occur naturally, such as molecular oxygen on comets and methane released by volcanoes. However, as methane does not stay in the atmosphere for a long time, we could conclusively say that the constant replenishment of methane in Earth's atmosphere was by biological process. Indeed, the combination of methane with either oxygen or ozone provides for a good case of astrobiology.

Magnetosphere: Just like Morkan, Earth has a rotating liquid iron core which produces a protective magnetic field

that surrounds the planet. This helps in deflecting and protecting Earth from Sun's radiation and solar wind: a stream of high energy particles traveling almost at 1000km/sec, wreaking havoc and causing destruction on the atmosphere of every body it encounters in the star system. We can safely conclude that had it not been for the magnetic field, earth's atmosphere would have eroded away ages ago, killing all life with it. The solar wind colliding with and being deflected by the magnetic field also produces mesmerising aurorae just like on Morkan.

Liquid Water: Finally, we come to what is probably the most important biosignature. Liquid water is important for two reasons: Firstly, water is a universal solvent, which means that it is that it is capable of dissolving more substances

Planet G4 would be a great laboratory for studying experimental terraforming

in it than any other known solvent. The greatest advantage to that is that liquid water can transport dissolved minerals from one corner of the planet to another and support life. Secondly, water needs to be in liquid form because solid ice traps nutrients and does not move. Liquid water carries the highest weightage in determining the HML of a body. Liquid water on Earth was first detected by observing the unusually high percentage of water vapour in the atmosphere.

Following the successful detection, observation, and interaction with life on Earth, SIPS now uses identical methodology to provide Habitability Meter Levels (HMLs) on four other bodies in the same star system as Earth. Bodies below are referred to with their local names and the star system is called Solar System.

Meter readings:

- Energy: Abundant
- Suitable Gases: Yes
- Magnetic Field: Yes
- Liquid Water: Abundant
- HML: 5

GS04 (Mars)

Being Earth's neighbouring but smaller planet, it has attracted a lot of attention from the natives and for good reason. Mars sits just on the outer edge of the Goldilocks zone and is rocky as well. It has confirmed reports of trickling salt water on its surface. There is barely enough heat from Sun, so it's much colder than Earth and definitely too cold to have oceans. There is a visibly remnant magnetic field. The magnetic field that once existed might have kept the planet warm enough to

contain life. Solar wind has since stripped all of its atmosphere away. Present life is most certainly absent, while past life could have existed. The magnetic field loss is still unexplained.

Meter readings:

- Energy: Not enough
- Suitable Gases: No
- Magnetic Field: No
- Liquid Water: Minimum
- HML: 3

GS05.04 (Europa)

Europa is a moon of the largest planet in the solar system coded GS05 ((translation: Jupiter). It has rocky interior but a water-ice crust. Its surface is filled with lines and cracks but it is the smoothest object in the solar system. This smoothness indicates
