Everything you wanted to know about PHP 7

>>The omnipresent PHP moved to version 7 directly from version 5. The update came out in December and we've allowed more than enough time for the initial set of kinks to be ironed out. Here's what you need to know - by Vishal Kumar More

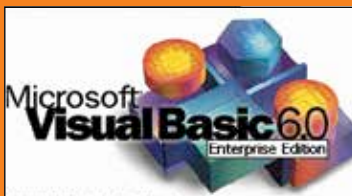

As per W3Techs, of all the websites in the world whose server side language is known, PHP powers 82.2% of the websites. Of these 82.2%, 80.72% of the websites are using PHP 5. The best of the CMS (Content Management System) available today – be it WordPress, Joomla, Drupal or Magento are all built with PHP. PHP 5 was released back in 2004 and since then minor releases kept on adding many exciting features to PHP, including support of OOP (Object-Oriented programming) and many other features associated with that. Until recently, the latest stable release version of PHP was 5.6 which was released in mid-2014.

Recently, the PHP community marked the release of its latest version – PHP 7. This new version of PHP brings along with it – dynamic performance improvements, minimal memory consumption, and a series of unparalleled language features to let you take your app to the next level. PHP 7 has brought along with it the all new Zend Engine 3.0 (not Zend Framework!). In comparison to PHP 5.6, apps built with PHP 7 turn out to be twice as fast in performance

and consume 50 per cent less memory. Thus, you can now serve more users concurrently, without upgrading your hardware. All thanks to Zend Engine. Aren't we already in love with it?

*Coding Matters
