Tomorrow's tech

designed by California based robotics company suitX, which designs and makes medical and industrial exoskeletons. For a sum of \$40,000, you can get an exoskeleton that is different from other exoskeletons that are being designed and prototyped in labs right now. It is operated via buttons on the attached crutches and the walking gait can be adjusted via an android app. But the most unique feature is the fact that this suit is modular and can be adjusted for tall people or children. suitX claims that this can last for 4 hours on continuous usage. Along with this, On 10th May, 2016, Ekso Bionics announced that it will be demonstrating the EksoGT robotic exoskeleton, the first and the only exoskeleton to be cleared by the FDA for usage with stroke patients

Your own Exoskeleton

If what we've been telling you so far has made you believe that you can't really get your own exoskeleton right now, think again. Kuratas, from Japanese tech

THE GREAT ROBOT DUEL CHALLENGE

Pretty soon, America will once again battle Japan. It's just that this time, the battle is between America's Megabots and Japan's Kuratas. Almost one year ago, Megabots had challenged Kuratas to a duel which was accepted almost immediately. Megabots is no small challenger and packs a heavy punch with it's arm cannon that can shoot paintballs at 120mph. Well, June, the promised month, is almost here. The question is, will they deliver?

company Suidobashi Heavy Industry, is a 120,000 Yen or ₹7 crore worth robot/armoured suit that is both maneuverable as well as weapons ready. Developed by artist Kogoro Kurata and roboticist Wataru Yoshizaki, this machine is heavily inspired from the artist's childhood fascination with mecha featured significantly in anime.

The machine/vehicle weighs about 4,000kg and stands at 4 metres tall. It can be operated by a person seated inside the body of the vehicle, and also remotely via almost any connected device. The onboard pilot interface is in fact a Kinect based device that incorporates motion sensing into the controls. There are several additions listed on the official website, namely twin 6000 round per minute BB rotor cannons, a water bottle or fireworks launching LOHAS canon, a humanoid hand called the "iron crow" that is used to lift heavy objects, and even a "Kuratas handgun" and a "Pilebunker". Rather than us explaining each of these additions, go to <http://dgit.in/KuratasExo> and finally design your own mecha (Cue Gundam opening theme!). If you do order one from the above link or from <http://dgit.in/AmznKuratas>, remember, good kids share their toys.

Should you suit up?

As it is with any piece of technology or science that augments human abilities or alters them, there is a question of ethics with exoskeletons as well. The positives are quite obvious, and somehow they manage to lead you to the negatives as well. The neural interfacing and muscle movement detection are opening new doors towards accepting human augmentation, and with the world coming to terms with genetic code alteration, the acceptance of exoskeletons in everyday life might act as the catalyst towards pushing cyborg research into full steam.

Most of the progress has been achieved by military and weapons research into exoskeletons. The power and impact that seems awesome inside an anime or a science fiction movie immediately looks dire and destructive when you imagine it being used in real life. We have already seen what some of the most powerful armies in the world have done to weaker nations in the last few decades, periods of relatively less global international conflict in human history. Consider this, if exoskeletons that are light and easy to use are finally developed, they will probably lead to an invincible army. The important question at that moment would no longer be how to make an exoskeleton, but rather, who made it first. 

The Kuratas looks like it jumped right out of a mecha anime series
