**A**lmost every piece of electronic circuitry is on the lookout to get connected right now. This is leading to the widespread emergence of Internet of Things, the connected network of objects that use sensors, actuators and transmitters to send and receive data related to the object itself. And to say that Internet of Things is still just a buzzword would be nothing short of idiocy. IoT has jumped way beyond smartwatches and has entered almost every industry that you can think of – from manufacturing to health. According to US Technology firm Gartner, the world will have more than 25 billion objects with computer chips within the next five years. There are real companies out there who are completely changing the way they function by incorporating IoT into their processes.

We are already at a point of time where your refrigerator can let you know when you need to make a trip to the local supermarket, and your kettle will brew your tea when you start from office. And pretty soon, we'll have smart fabrics monitoring our health and metabolism, smart sofas correcting our posture and maybe even some smart people around you! And if the idea of being involved in creating such a world, where everything you interact with is connected to everything else, excites you then driving your career towards IoT is the right thing to do.

### What exactly is an IoT career?

Unlike most other industries, it would be wrong to identify IoT as a complete industry by itself, with its own specialisation in terms of learning. Yet, one of the first things that come to a student's mind when choosing a career path is the qualification and specializa-

tion needed for it. From that perspective, these are mainly the different verticals that one can prepare for –

**Data Analytics** – One of the key features of an IoT system is the amount of data generated. With the sheer number of devices involved, and nothing to make sense of it, it's as good as a pile of junk. Data Analytics are in high demand within the IoT industry with expertise in both structured and unstructured data. The structured data comes into play from specialised sensors that not only send values but also the identifiers for the type of data. Big data expertise and experience would be a strong factor in getting opportunities in this segment. The amount of data that will get generated once you get connected will be huge, and there will be a need to analyse it quickly in order to get insights out of it. People are talking about using predictive, cognitive, prescriptive and descriptive methods to do that, and
