

SANITATION AND HIGH SPEED INTERNET

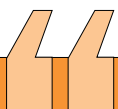

In India, sanitation and safe drinking water in urban and rural areas are two big concerns for the government. The current use of technologies to purify water is restricted to chemical treatments and water purifiers, but with the use of nanotechnology solutions, we can make it cheaper and provide improved water filters to all. Nanotechnology-based filters use non-scaled membranes which are made of graphite materials used in pencils; and are way cheaper than conventional methods. Sanitation is one of the most prominent issues in India. Nanotechnology makes it possible to create waterless toilets to treat waste and banish smell. These are based on innovative technology in which toilets use the rotating mechanism to move waste into holding chambers containing nano-elements and water can be

eliminated as vapour. Also for successful implementation of digital projects initiated in the country, it is imperative to find a quick fix solution to improve the coverage of internet. India can't be truly digital till we have ubiquitous connectivity. Li-Fi (Light Fidelity) is a technology that can become mainstream, to improve internet speed, as it provides a basic medium i.e. LED bulb acting as routers and ordinary light being used as a medium instead of radio waves enabling high speed data usage."

Partner and Head - IT Advisory Services, KPMG in India

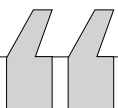

ACCESSIBLE TECHNOLOGY

At Intel India, we believe that creating technology relevance is the biggest challenge in a vast country like India. The government's vision of Digital India also relies heavily on the premise of bridging the digital divide, wherein every citizen is digitally connected and understands how technology can positively impact their lives. To make this possible, we need to build platforms and solutions that bring relevant content, ease of access, and connectivity, especially to non-urban citizens in the country. Taking technology to the grassroots and empowering every citizen to educate, innovate, and express themselves, will be fundamental in achieving inclusive and sustainable growth for India. We believe that public private collaboration will make this empowerment possible, which is why Intel India's endeavour is to build an ecosystem that makes technology accessible and affordable for citizens."

- SANDEEP AURORA

Director, Marketing & Market Development - Intel South Asia

CONSISTENT POWER SUPPLY

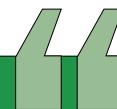

With technology taking centre stage in our lives, the world is moving towards internet of things and machine to machine interaction. India still dons the hat of having the slowest internet connectivity in Asia-Pacific as per the latest report by Akamai. This is indeed the biggest impediment not only to us as manufacturers but to the consumer as well. One is unable to fully utilize innovative technologies in any product due to weak/no internet availability. So there is an urgent need to boost the internet connectivity and to ensure a fair distribution of internet across country. This will also help the brands to enhance their after sales services as well.

Another area that needs immediate attention is inconsistent power supply, especially in rural India. The consumers find it very difficult to opt for products that are heavily dependent on steady power supply. To overcome this, it is important that companies go that extra mile to install components that can endure such conditions and withstand power issues. Government too should invest in alternate technologies for power generation like Solar and Wind which will help meet the excess demand for electricity and ensure continuous power supply. Further the government should also invest in building the infrastructure so that the industry flourishes."

HARNESSING THE CONTENT EXPLOSION

We are consuming hundreds of petabytes of data every month on our telecom networks for watching videos (and yes we all still face problems completing a phone call without a drop). Now imagine, what life will be when there is truly world-class 4G network (and we know that is really round the corner). And then we talk 100 Mbps+ Fiber-to-the-home networks (given that most of us struggle with between 2-5 Mbps lines currently, we cannot really think of that world yet – but that too is near).

Technology doesn't only allow users to access Video or Audio Streaming platforms (like Netflix, Youtube, Pandora or VOOT), it also helps create a whole new media consumption ecosystem and build reach globally at lightning speed. We share content trailers, we play Shazam songs and we stream when we want, where we want.

Backed by easy access to broadband and smartphones, digital media is heralding in a content explosion. Content creation is now democratised – we are all creators, distributors and consumers at the same time. Now, let's not mistake that to mean that anyone with a smartphone can replace the experienced content creators in traditional media. Not at all!

However, it does mean that the barriers to distribute content have been taken away by the internet and cheaper tools are available to create – hence there are more creators who need not be always backed by big studios, TV stations or music companies. That keeps everyone on their toes and trying to innovate at all times. There has been no better time as a user to get this quality and variety of content and no better time to be a creator – all backed by technology."
