Tomorrow's tech

the brain. That's why they start charging (as fast as they can) at the slightest hint of prey, but just quietly shuffle aimlessly about otherwise. This is also why you are hiding in a trash container in the apocalyptic future. It takes cognition to even consider the inside of the container, it has a lid which takes coordinated motor skills to open, and the stench covers for you in case you fear the ones with sensitive noses.

Also, human zombies are generally not peaceful, and always hungry. Their insatiable appetite can be attributed to improper functioning of the hypothalamus, which controls satiety. Imagine being perpetually hungry... But that's not why they're always angry. Our attitude about our situation is governed by the amygdala, the seat of the famous 'fight or flight response'. Zombie brains appear to constantly be in fight mode, perhaps owing to an overactive amygdala. They never recognise anyone, even if they happened to be family when alive. This disease is called prosopagnosia, or face blindness, and affects many healthy individuals, hampering their ability to recognize or remember the face of any person. Despite all these frustrations, zombies are different from humans also because they can hardly express any of their issues. Almost any domestic animal has more variety in their auditory output than a zombie. This is scientifically plausible as a combined effect of Wer-

brought back to life incompletely. Just like that clinical trial..

Foreword to the future

Bioquark and Revita's ground-breaking clinical trial is yet to publish any results, as the experiments have hardly begun. The procedures being tested to bring back the dead involve injecting a solution of stem cells, proteins, peptides and other activators into the brain and spinal cord, shining lasers on brain tissue through the skull, and stimulating electrical nervous pathways with magnetism. Stem cells are already known to behave in miraculous ways, specialising into any cell that is required in the vicinity. The other components of the solution include activated proteins, which are the factory workers of the cell, and also mRNA and other primordial genetic soup. The idea is to artificially create the conditions that will trick the dead brain into growing once again, as if it was in the body of a newborn child. Dr. Bansal will study the effects of these treatments on the comatose patients over a timespan of six months or more, observing the neural regeneration, if any. The results of the study will confirm whether or not reversal of brain death is possible. While the ReAnima project almost certainly won't achieve results close to anything like reviving a dead person, it will certainly help pave the road towards that end. If it were anywhere close to its goal, the elite of our world would surely have taken it for themselves and hidden it from the world.

In the future, companies may never have to rehire again!

nicke's aphasia and expressive aphasia, rendering the brain practically unable to comprehend language and communication. So there you have it, a zombie. Some unfortunate human who died incompletely, or more likely, died and was

Soon, there may be other ambitious individuals and companies who are willing to take advantage of the regulatory lax in our country and try out their own procedures towards unknown ends. Perhaps some will be noble and true in their quest, like a company who wants to test living cadavers for mainte-

nance and use them as an unlimited blood supply, solving a crucial limitation in the state of our healthcare systems. Yet others may not be as nobly motivated, and the opportunity for a real life super-villain would be ripe!

To zombie or not to zombie...

Maybe the results will give us some clues towards the procedure for a successful starfish-like regrowth and reanimation. Once that is determined, the procedure and its ingredients could be written in the genetic code. Furthermore, the procedure could be tweaked to incorporate the required zombie characteristics, which would give us the genetic zombie code. Researchers at the JC Venter Institute in the USA have already successfully synthesised life, by creating a living strand of DNA that doesn't exist in nature. So it isn't much of a stretch from there to synthesize a virus or bacteria containing the zombie code and design it to spread as rapidly as possible. If you like the sound of being worse than Hitler and actually plan to do this, don't forget to synthesize the cure, which you can then sell to the highest bidders. After that, it's a short climb to your local water tank, or a small bribe to the technician who cleans the air conditioning of the metro..

While some may argue that the world is already filled with mindless zombies economically manipulated into being slaves for the few at the top, things can certainly get a lot worse! If you don't plan on joining the crowd and becoming a zombie, best start running a lot, take up a martial art, and maybe learn how to throw knives. Either way, if it does come about, your best hope for survival will be the zombies' favourite food - Brains! 🧠
