

defined in this game we just generate a single tone of frequency 1500. This generates a 'ting' sound every time the ball hits one of the bricks. We could similarly add sounds for whenever the ball hits the wall or for Game Over etc. However, we shall stick to using one sound for this demonstration, i.e. only in case of collision.

Doing this is as simple as calling a function that accepts a single parameter as frequency from within the collisionDetection() function.

```
oneNote(1500);
```

which in turn executes our same old function of playNote() once with this predefined frequency:

```
playNote(context, node, 1500, startTime, duration);
```

More interesting components of Web Audio

- **DelayNode:** An AudioNode audio-processing module that causes a delay between the arrival of an input data and its propagation to the output.
- **StereoPannerNode:** It is a simple stereo panner node that can be used to pan an audio stream left or right. `MediaElementAudioSourceNode`
- **MediaElementAudioSourceNode:** It is an AudioNode that acts as an audio source consisting of an HTML5 <audio> or <video> element.
- **MediaStreamAudioSourceNode:** It is an AudioNode that acts as an audio source consisting of a WebRTC MediaStream (such as a webcam or microphone).
- **AnalyserNode:** It is able to provide real-time frequency and time-domain analysis information, for the purposes of data analysis and visualization.
- **ChannelSplitterNode & ChannelMergerNode:** These interfaces respectively separate the different channels of an audio source out into a set of mono outputs and vice-versa, i.e. merges different mono inputs into a single output.
- **AudioListener:** It represents the position and orientation of the unique person listening to the audio scene used in audio spatialization.

BROWSER COMPATIBILITY

Edge	YES
Chrome	YES
Firefox	YES
Safari	YES
Opera	YES
iOS Safari	YES
Opera Mini	NO
Android Browser	YES (since 51)
Chrome for Android	YES
IE	NO

Conclusion

In our examples we have barely touched the API, but by now, we should have a working example of the Web Audio API in front of you. Well done! Very soon, you will be able take this forward and who knows, you might even build a brand new application with this that will change the way we all use the web.

Internet today is changing rapidly. With the advent of better performing browsers, newer technologies and high speed internet connections, the end user demands and in fact deserves to get a better experience in these changing times. Such an experience should not be linear in terms of options available to the user. Therefore, let us all strive to make the web a better and richer place, both aesthetically as well as performance wise. It is up to us developers to ultimately use these emerging technologies and provide a pleasant experience to the users. And that involves all types of interactions and content - text, pictures, audio as well as video along with interactable web UI.

With this tool under your belt, unleash your creativity on it. Some of us see coding as a hobby, some as a means to solve a problem, some as a skill to earn money with. Over all of these, code has always been and shall always be a work of art, and the Web Audio Interface is just the voice that this form of art needed in order to make some noise.. So go ahead, pick up your tools, and create some music! When you do develop your own WebAudio implementation, do share it with us>
