

you will be shocked how often they work, which explains why people still keep trying to run these scams. Yet, some contextual ones have been really successful recently. Take the Hillary Clinton – ISIS hoax email that actually got a lot of Hillary-haters to click on it.

It is pretty easy to create a phishing email. Just get a custom domain, or an official sounding email ID, such as 'noreply.logininfo@gmail.com' (that's probably already taken), and draft an email that sounds really official and

job of protecting them. This might be true 99% of the time, but only once can be bad enough. You could always tell them to turn off their antivirus when installing a (*cough*) free game!

Some fun applications you can share with them are Fake Format and Fake Delete, both of which imitate actual Windows dialogs and applications and appear to delete your directories and files. You can even create a friendly looking batch file ("Get a free game" anyone?) that throws scary looking

Most patches to operating systems and software are actually security and stability changes, that unfortunately gets the most rejections. This is a complex and dangerous exploit that not everyone can pull off, but if you're able to understand code, it shouldn't be hard for you to find places where the latest exploits are discussed.

Then of course, there are the full-fledged exploit kits that are available which let you take advantage of such bugs. Be careful though, because if you don't know what you're doing you could end up hacking yourself and giving access to some real hacker out there – you don't want to end up being the n00b yourself!

INSTALL RANSOMWARE

Ransomware is easily available online, and if you look hard enough, you will find several harmless variants. If you don't want to mess with actual malicious software, you can fool a n00b into believing that you have installed ransomware using PowerPoint!

All you have to do is create a ransomware announcement screen. remember to use dramatic language and visuals, because the aim is to scare people into submission. Text such as:

All your files and documents on your computer and connected network have been locked and encrypted. ID: 45GHs78Q
A special self destruct code has been used to encrypt your data with our exclusive software and there is NO WAY to decrypt it without your private key! Do not attempt to press ESC or any other Key, as it will:-

Destroy the private key ---
distribute your files on the dark net --- Software to unlock your computer will cost higher
Send an email with unique ID given above to <use the email ID created earlier here> within 72 hours if you want your data. We will send one file to you for free once we receive the email. Have fun!!

When you have created this slide, go to the Slideshow tab, and under the

Trust me, it was probably more secure in 1995

states that the receivers need to share their credentials for security reasons (the irony of it!!). Something like this should get you the password you want:
to: noreply.logininfo@gmail.com
Subject - (/rt -dhx UID_pwd)//Don't change this subject line
Body -

<your email ID><space><your password>
<target email ID>
<set security key>
end of email

You will be surprised at how many credentials you receive. Don't believe us? See how many people fell for the 'Facebook privacy declaration' post. (<http://bit.ly/1A1WrZe>).

GET THOSE PENDRIVES

Most people don't think twice before sharing their pen drives or external hard drives around. In fact, if you claim to have a decent copy of a good movie, people will throw their drives at you! The assumption is that their antivirus will just do the

DOS messages in the method mentioned here: <http://dgit.in/FakeVirus>

CLICK-HAPPY

Click-happy folks can be an endless source of pleasure. They just download anything you send them, and click when you tell them to click – they're so trusting and naive! They are easy targets for scams that spread malicious code via document macros, which most people do not disable explicitly. You should find it easy to send such an email to them. Keep a harmless macro that only issues a huge warning to them in a document and email it to them. Sit back and watch as they (hopefully) learn their lesson.

POKE THE UNPATCHED

Patches are seriously ignored by a whole lot of people, because hitting the 'Not now' or 'Ignore' button is much easier and time saving than the responsibility of sitting through the upgrade.
