

You may never need to ask the system, instead the system might warn you...

- **License plate reader information** – To track movement of individuals
- **Environmental data** – To track changes in Radiation levels etc.

And as more and more agencies adopt the same PCA system, the data sharing between individual systems would further enhance accuracy levels. And to increase the amount of data, all the above mentioned sources of data would be encouraged to hoard and provide even more historical data. Which brings us to the ever popular discussion on privacy. As we stand now, you can't expect privacy for everything that occurs in the public domain. So will these systems obtain information from your private devices? Soon enough, yes. Or quite probably they already are. While national intelligence agencies of first world countries have been mining and generating metadata from your personal devices for a few years now, these PCA systems so far don't seem to

do so. Current systems rely on publicly available data but it won't be long before you're given a choice to voluntarily surrender your privacy to help such systems improve accuracy.

ARE MACHINES BIGOTS?

One of the biggest arguments against law enforcement agencies is that the officers of the law tend to be biased towards a certain race or even community because historical data says so. So would feeding a PCA system the same data cause it to turn into a racist and bigoted system like what happened with Microsoft's AI chatbot – Tay. Tay started off an experiment in conversation understanding and according to Microsoft, the more you chat with Tay, the smarter it becomes at making conversation. It's a pity that Twitter went wild and started chatting with Tay using misogynistic and racist remarks. The AI soon

picked up on this and assumed it to be part of a normal and casual conversation. And soon enough, it went from an innocent chatbot to a full-blown bigot that could out-nazi Hitler himself, all in under 24 hours.

So when you take historical data which says that members of a certain community have a greater propensity to commit crime, will an AI immediately flag him or her down? Not quite so. As the system learns more and more, it will make predictions and flag down individuals for officers to intercept, and the moment it receives feedback on whether the individual was indeed a threat or not, the system learns again. Soon enough, the initial pattern which cause the system to flag down the individual will be modified and a new pattern will emerge. Thus, evolving and becoming more accurate. Over time, the system performs a 'balanced assessment of relative weights' which is to say that a person with no criminal history acting in a suspicious manner will not be flagged down. Such as a school teacher keeping the car motor running while parked in front of a bank will not be flagged as a getaway vehicle.

It should be noted that these systems don't pass judgement but merely calculate the propensity of an individual to commit a crime based on their recent behavior in public. And current gen PCA systems like Hitachi's Visualization Predictive Crime Analytics simply flag down such areas which results in increased police patrolling. Such directed patrols have proven to reduce crime statistics in hot spots according to studies conducted in the USA.
