

Capture the entire webpage

Taking screenshots is easy as mentioned above, but what if you wanted to take a screenshot of the entire page? ONE Browser offers the option to screen captures of the visible area, selected area or the full page.

AUDACITY

If you're into sound editing, you must have probably heard about Audacity, and it's highly possible that you're already using it for your projects. Whether it's sound mixing, voiceovers or podcasts, it does the job for you easily. The open source and free software is so powerful that it's recommended as a strong alternative to even the commercial audio editing software out there. We have covered Audacity several times before, so here's a quick rundown of the most useful tips and tricks offered inside the software. You'll come across tips which are directed more towards creating podcasts and voiceovers for YouTube videos.

Amplify your tracks

This may be the most common feature used in Audacity, in fact many specifically have downloaded and installed this software just

to amplify their recordings. This feature is useful when your recording device has a lower capture volume. It also works the other way, so if it's too loud, you can decrease the peak by entering a negative value. And it's fairly simple. Once you've opened the audio track, you can both select the entire track or just a portion, and then go to **Effect > Amplify**. Then you can enter the Amplification value in positive or negative based on whether you want to increase or decrease the peak.

Change the pitch

Ever wondered how to convert a normal voice recording into that squeaky and chipmunky pitch? It's really easy on Audacity. With an area selected in the track, go to **Effects > Change pitch** and move the slider or enter a value in Percent Change under the Frequency section. You don't need to fiddle around with the top section if you're only dealing with a normal voice recording. You can increase and decrease the pitch by adding in a positive or negative value respectively. Higher the pitch percent change, the more squeaky the voice, whereas lesser the pitch, the deeper the voice.

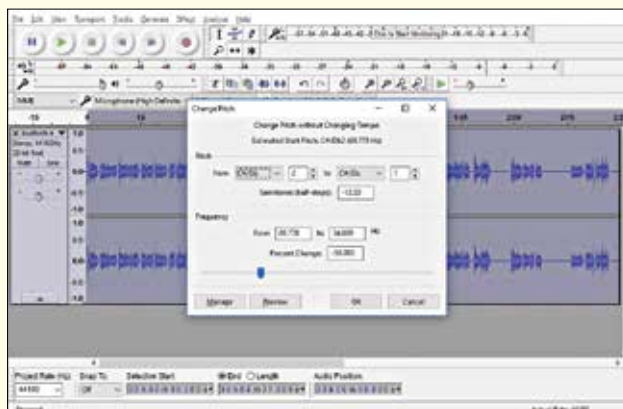

So now you know how to get the chipmunk voice.

Removing silent portions mid-way

While recording for your video voiceovers and podcasts, there are silences in between as you speak throughout the length. The final version sounds awkward hence it's always better to get rid of these silent gaps, to improve the flow. You may wonder that you would have to grind and remove all the

select the silent area where you don't have any necessary sound. Then go to **Effect > Noise Reduction** and click on **Get Noise Profile** under **Step 1**. This is how it acquires the ambient noise signals which can be filtered out. After getting the noise profile, open up **Noise Reduction** again and hit **Ok** in the **Step 2**. Now the track will sound significantly noise free if you play it.

Play around with the pitch change percentage until it sounds right

silent portions by manually selecting and deleting them. But Audacity has a tool to achieve that. Go to **Effect > Truncate Silence** and select **Truncate Detected Silence** under the **Action** section. Once applied, you'll notice that all the silent gaps have been removed. If you want to get more specific to the level of silence you want to achieve, the **Detect Silence** section in the same menu lets you select the level of silence you want to remove. But if you're satisfied with the default setting, then you don't need to fiddle around with it.

Noise removal

You're done recording your clip but when you play it back, you hear a lot of ambient or background noise that the mic picked up. Obviously, it's an unwanted noise and it's easy to remove them. First

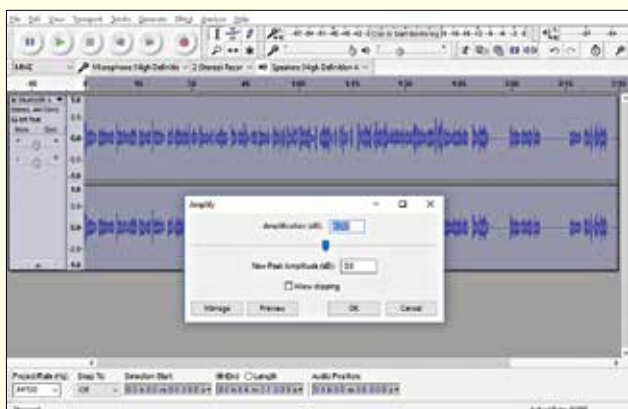

Normalise audio levels

To achieve good quality audio in voice recording, it's essential to maintain a steady and constant distance from the mic. Otherwise, you might notice a random rise and fall in the sound levels which sounds really bad. Audacity has a tool built-in that normalises the varying sound levels so that you achieve a favourable audio track. This works really great if your audio is too loud and you need to bring down the levels. Go to **Effect > Normalize** and add the required value, varying from -3dB to -6dB and so on, until you hit the right spot.

Change the tempo

You might not be happy with the tempo of the audio you recorded and are considering re-recording at a different

The amplification tool is very easy to use in Audacity
