

Fake accessories on Amazon

Nearly 90% of the Apple accessories sold on Amazon are fake, according to a legal document from Apple obtained recently. <http://dgit.in/iAccz>

No refund for the Gear VR

Samsung is offering a refund for your Galaxy Note 7, but not the Gear VR you received with it. <http://dgit.in/SGrVR>

Dual Camera Phones

HOW WE TESTED

Our test process began by taking each of the smartphones out separately to shoot photographs. This got us familiar with the camera app interfaces and the way the cameras function. Following this, we chose to try out shooting random moments to see how fast the smartphone cameras shoot photographs.

Our next step involved shooting with the three smartphones at the same time. This was the most crucial test of this comparison as it gave us the comparative details of the three smartphone cameras. We took out the smartphones to shoot in numerous

conditions, include daylight, overcast, diffused sunlight, evening, night and indoor. The idea was to find out how the smartphones react to different situations, hence determining which one is more versatile.

We also shot with subjects at varying focal length. Shooting with subject at close-up was crucial, seeing that bokeh forms an important part of these cameras. Following all of this, our inspection process began on a colour-calibrated 2K resolution display, which delivers trusted colour performance. The colour details, along with subject sharpness, white balance

and image noise are all increasingly noticeable when we apply 100% crop on the photographs.

Other factors like shutter response and zooming also played a part in our testing process. Seeing that the Apple iPhone 7 Plus now has 2x optical zoom, we put it to test against the other two's digital zoom photographs to find out whether the presence of optical zoom proved to be beneficial. The final rounds of testing include repeating the environments already shot in, along with taking a few extra photographs to rule out any exceptional or unnatural result(s) obtained.

WINNER

It is indeed the Apple iPhone 7 Plus that takes home the trophy in this comparison. The latest iPhone by Apple produces rich, true-to-source colours, keeps image noise to a bare minimum, and shoots photographs with high sharpness. The f/1.8 wide angle lens already helps it create finer background blurs, although the bokeh mode has not even arrived yet.

The Apple iPhone 7 Plus is also the fastest shooter of the three dual camera phones that we compared in this story. Throughout shooting for images for the purpose of this analytical tests, we realised that the iPhone takes the least amount of time in focusing, opening of the app, shooting and saving of an image or video file. This may contribute into the buying decision behind the three smartphones, as the iPhone notably provides a cleaner user interface, albeit with lesser number of settings that can be accessed and tweaked in a photograph. That's right, simplicity of use comes at the cost of lack of pro mode, but that can be easily fixed by downloading an app off the App Store.

The Huawei P9's strength lay with image details, while the Honor 8 is still the most affordable smartphone with all of these elements in its list of features. But, as far as outright photo

quality, along with the implementation of dual-cameras and every other detail is concerned, it is the iPhone 7 Plus that wins this shootout, by a comfortable margin at that, too. **d**
