

anyone would want to do that or maybe you just want the assistant to stay out of your life (account), you can simply do this by swiping left > Settings > Disconnect Google Account. Or you can also add another account tapping on Google Account.

Play games

You can also play single or multiplayer games in Google Allo. To start playing single-player games simply type “play games” in your Google Assistant and it will recommend you games to choose. Select any genre and it will provide you with a new list of games that you can select and play. To start playing multiplayer games with your mates, simply type

“@google” and “play games” in the particular chat. The assistant will suggest you some multiplayer games that you can play together with your friends. You can also compete with them for rewards using leaderboards.

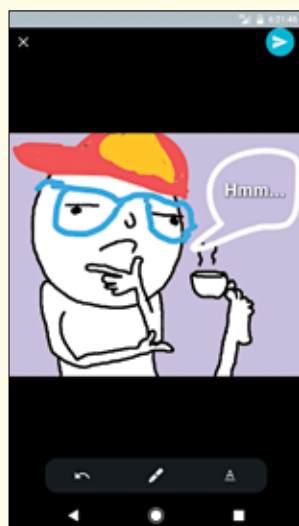

Draw on images

You can doodle on top of images or add custom text before sending them. Simply select the particular image you want to send by tapping

on the “+” button on the message box where you will have five options – keypad, camera, images, stickers and google maps. You can go to the image section (or camera if you want to take a new one) and select the particular image you want to send. After selection, you will find an option where you can edit the image. You can draw on the image in different colours or even add a text to it.

Block contacts

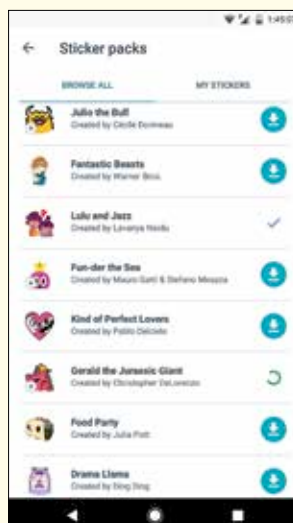

This is sort of a hidden feature in the application that you can use to block unwanted contacts in your chat. However, in Google Allo you can only block someone once a chat has been started. There are dif-

ferent steps involved in how to do this in Android and iOS.

To block someone in Android, you need to tap and hold the particular chat of the contact you wish to block and you will get a pop-up menu. Select “Block”.

Similarly, in the iOS version of the app, open the chat of the particular contact you wish to block. Then, tap on the profile picture of the contact > View (Contact) profile. In the profile page, select the block option.

Get stickers

Google Allo has dozens of sticker packs that you can download from the app. To start using them, just tap on the “+” button from your message box and select the sticker you want to use. To download even more just tap on the add icon. From funny cartoon GIFs to cute bunnies or even the new movie “Fantastic Beasts and where to find them”, you’ll find them all. These sticker packs are specially hand-made from different artists and they can really help brighten up your conversation. In addition to that, Allo also has a “Smart Smiley” button in the app which can bring up a list of suggested emojis and stickers based on the context you type.

PC STATUS MONITORING

Keeping an eye out on your system’s health is a recommended measure if you wish your components to live a longer life. System monitoring also helps in determining several errors and issues you might run into while playing a game or editing a video. For instance, your system keeps automatically shutting down as soon

as it boots up. You wonder whether your processor needs to be replaced already but after opening up temperature readings, you realise that your processor is heating up crazy and needs an instant reapplication of the thermal paste. This and more such problems can be tackled with the following methods and tools to monitor your system status and health.

Monitor system temperatures

There are a couple of free and paid software on the internet that you can use to monitor your computer’s CPU and GPU temperatures, but the one we recommend is Core Temp. It is a com-

pact 1MB fuss free software that displays your CPU and GPU temperatures using the DTS (Digital Thermal Sensor) implemented in your computer.

Verify system and device specifications

By default, you can check your computer’s specification by right-clicking on “My Computer/This PC” and selecting Properties. This will show you a list of your computer’s specifications also known as System Properties. A more detailed information about your display devices can be viewed by opening ‘Windows+R’ and running the command ‘dxdiag’.
