

To find the list of other devices installed in your system such as your graphics card, network adapters, additional peripherals etc, click the Device Manager link on the left list of your System Properties or simply run the command 'devmgmt.msc' from the 'Windows+R' box.

If you need more granular information about your CPU and GPU, downloading and installing CPU-z and GPU-z (both are individual tools) is recommended.

Display in-game FPS

Nowadays, most of the newer games have a "Display FPS" option in the game's settings and you can enable this to monitor your game's FPS count. If the game you play doesn't have a built-in

FPS display you can do that by trying some of the following software:

Steam: This feature applies to only the games that are run through Steam. You can enable this feature by

going to your Steam menu > Settings > In-Game > In-game FPS counter. You can also try and use this feature to display for some of your other non-Steam games. To do this, you need to add the game to your Steam library. Games > Add a non-steam game to my library and launch the game through Steam.

NVIDIA GeForce Experience: If your PC has an NVIDIA graphics card then you can also use the GeForce Experience software to display the in-game FPS counter. You enable the overlay by opening the Geforce software > Preference > ShadowPlay > FPS Counter and choose the position where you want it to display on your screen.

RadeonPro: In the same way, if your PC has a dedicated AMD graphics card you can use the RadeonPro software to display the FPS counter in games. To enable the FPS overlay, simply open the RadeonPro software > Settings > FPS counter > Choose the display corner and save.

CAM: Other than just overlaying the in-game FPS, if you wish to also look at the

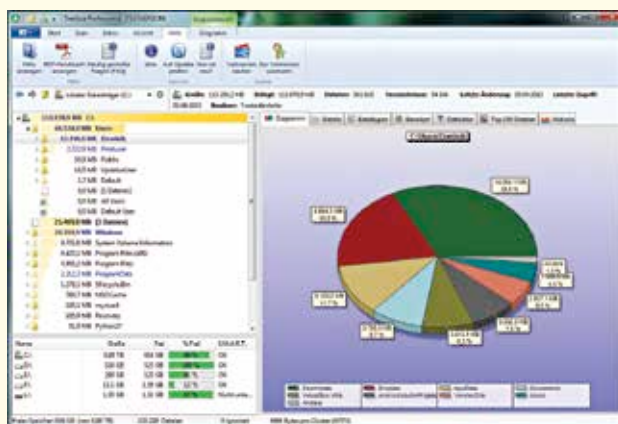

CPU/GPU usage, temperature, clock speed and also the memory and VRAM usage, CAM from NZXT will let you monitor all these parameters in-game. The software also lets you

select the parameters you want to be displayed.

Analyse occupied disk space

Have you ever run out of disk space in your computer and had no idea where all the space went? And then when you sat down to find out, did it seem intimidating to browse through the endless number of folders and files in your hard drive? TreeSize

gives you an idea on which folders are taking up too much space in every drive. It also sorts out all the files based on their extensions, so in one place, you can have all your audio files listed and you'll be able to browse through .mp3, .wma and .flac files easily. This really does help a lot in a storage crunch.

Monitor network and data usage

Windows retired the feature of desktop gadgets where you could have third-party gadgets installed to monitor your network activity. So, you'll have to open up Task Manager and navigate to Performance > Ethernet to track your download and upload speed. One interesting feature introduced in Windows 10 is Data Usage Overview that can be easily

searched in Control Panel or directly in the Start Search tab. Here, you can view the data used by individual software on your PC and determine whether a certain software is suspiciously using too much data.

Track active connections to PC

If you found something fishy going on through certain applications and want to

track what kind of connections are being established to your PC, you can use the netstat command from the command prompt. Run Command Prompt as Administrator and enter the command `netstat -abf` and you'll be given a list of all the established connections. Here, `-a` will display all the connections and ports that are listening, `-b` lists down the application that has an established connection, and `-f` gives you the entire DNS details to where the connections are going. To make it easier, you can output the entire listing into a text file with the command `netstat -abf > connections.txt` and the text file will be saved in the same directory. You can later use this text file for further detailed analysis to help you perform your monitoring exercise.
