Lost Android passcode, a conked memory slot, the notorious system32 error and more such suffering

This month we came across our readers facing problems on their PC on both hardware and software; along with smartphone issues

Q A foreign problem

Hey Guys!

First of all, I love Digit and I'm totally addicted to it. My problem is that I have a Xiaomi Redmi Note 4 which I bought from China (as it is not yet released in India.). I switched off the phone and after switching it back on, it asked me for the backup password instead of the fingerprint. When I entered my correct password, it is not accepting it and due to this I am not able to unlock my phone. I tried to search online for an answer and it suggested to switch off the phone, press the power and volume up button for ten seconds after which the recovery mode can be accessed. But when I did that instead of the recovery mode, I got a picture of the phone and the charging cable beneath it. I also tried contacting the Mi customer care in India, but they said that since the Redmi Note 4 is not yet launched in India they can't help me. In fact, everywhere I go, I get the same statement. I am really frustrated that I have got such a great phone, yet still I am not able to use it. Please help me to get out of this mess. You guys are my last hope.

– Shaurya

A Hey Shaurya,

It used to be easier on devices running Android 4.4 and below, but after Android 5.0, they removed the option in an attempt to increase security. The only way for newer devices is to factory reset your device which means that you'll be losing all your data. To reach the factory reset screen, you have to enter the custom recovery of the phone and for that you need to press the power and volume up hardware

buttons to activate it when the phone is switched off. If the charging icon is coming up, then you haven't reached the custom recovery. Try different variations with the hardware buttons such as power and volume down button or power and both the volume buttons. You can also try keeping the power button pressed for around 15-20 seconds to reset the device (although not all devices follow this). At the customer service, explain your exact problem and request the staff to help you out.

Q Socket trouble

Sir, I have a problem where one of my RAM socket isn't working. How do I fix it? My PC specifications are as follows:

- CPU: Intel Core i5-3470
- RAM: 2 GB
- GPU: GeForce GT 610

– Aditya

A Hey Aditya, looks like the socket has failed. To determine whether your socket or RAM module is faulty, you should try inserting your RAM stick on another socket or a friend's motherboard. The testing depends on the number of RAM sticks you have and whether your motherboard has more than two slots. If you're using just one RAM stick, which works fine, then you should simply switch to the other slot. If you have two RAM sticks and don't

RAM socket failure calls for a new motherboard

have more than two RAM sockets, then you'll have to use just one stick. The only solution would be to buy a new motherboard if you really need the other RAM module.

Q Kali-brated network card

Hey Team Digit,

I have a Killer Gigabit network card to reduce my ping while gaming. It's pretty good for reducing lag in gaming, so I was thinking whether it can be used in Kali Linux for better performance in monitoring mode but I don't know the concept of the Killer Gigabit card and how it works. So I kind of feel stupid about asking this question. I'm currently using an Intel Wireless 3165 adapter. I have an MSI GE62VR Apache Pro. So, if I can use the card in Kali Linux, do tell me how to change the default settings so that I can switch the network card. Thanks.

– David Terros

A Hey David, you shouldn't face any problem running scans and collecting wireless data on Kali Linux with your network card. Use the appropriate kernel version since we updating the kernel might affect compatibility in Kali. Here's a quick guide on how to setup an external network card: <http://dgit.in/NtwrkCrkKaliLinux>.

Q The forgotten settings

Sir, today I was changing the settings in my BIOS but can't recall what I changed. It shows an error mentioning "DRIVER_IRQL_NOT_LESS_OR_EQUAL". On restart, each time it is dumping physical memory and restarting. Please help me.
