

2017 for developers

>> Here are some of the key trends that have shown promise for the coming year → by **Mithun Mohandas**

A lot many developments have happened over 2016, quite a few trends have been over-hyped, with Big Data being one of them. And now with that having died down, the industry is making actual progress. Aside from lacking the right infrastructure and resources to base the industry on, these few years have only been good for the conglomerates that had the money to actually put big data to use. With really fast memory having arrived and compute hardware with large caching becoming more affordable, 2017 looks to be the year when we're going to see the democratisation of big data. Anyone can easily afford consumer grade compute cards from NVIDIA or AMD and get started with the number crunching. Moreover, we now have access to Machine Learning tools that have a much more beginner-friendly learning gradient.

So what do we expect from 2017? Read on...

There shall be one

This last year quite a lot of proprietary Machine Learning software ended up getting open sourced by the giants from Silicon Valley. Elon Musk backed non-profit called OpenAI was set up with the aim of building AI that is human friendly. Microsoft open sourced their Cognitive Toolkit (CNTK), Facebook has been putting its weight behind Caffe and Torch while Google

has open sourced its TensorFlow and DeepMind projects. Baidu, one of the biggest entities working on Machine Learning has also open sourced its set of libraries under the name PaddlePaddle. And lastly, Amazon has integrated MXNet into their AWS ML platform.

With so many tools getting open sourced, the community is slowly going to get its hands dirty and from among all these

Google open sourced DeepMind

will arise only one. While every Machine Learning library has its pros and cons, there are other factors that will come into play when developers start playing around with ML. These libraries will proliferate the developer community and at the end of 2017 we shall see one particular library becoming the gold standard. This gold standard will then be adopted by all major XaaS providers and will be better integrated with their platforms. Data Sets for these ML platforms will also become

*Coding Matters

*OpenAI's AI training

>> Universe is a software platform that allows any user to measure and train an AI's general intelligence.
