

VirtualBox 5.1.12

Oracle announced the release of their new VirtualBox 5.1.12 with Initial Linux Kernel 4.10 support <http://dgit.in/Virtualbox5>

Public shaming gamers

Capcom will publicly shame players with profile icons for intentional disconnects and ragequitters. <http://dgit.in/StrtFghtrV>

Gaming Mice

have been added to make it easier for you to decide on your next mouse.

ASUS Cerberus

The Cerberus is an entry level gaming mouse from ASUS. At this price range, you can't expect high sensor accuracy. In fact, we observed the tracking and malfunction speed was pretty low (around 1m/s). Once the mouse crossed the tracking speed, the sensor failed to register further and only started detecting again after it dropped below the threshold. We couldn't test acceleration due to the low malfunction speed, but we didn't experience any acceleration in the lower speed range. At lower speeds, the mouse had great accuracy. The shortcoming of the sensor to read data at higher speeds should practically concern only those gamers who play in low CPI levels. The comparatively high lift-off distance will make aiming difficult for gamers who're used to that technique. It has an ambidextrous design, offering comfortable grip for both claw and palm grip.

Cooler Master MasterMouse Lite S, S and Pro L

The Lite S is a comfortable mouse for people with small hands. It has a nice matte finish and on first glance, it looks and feels like a premium mouse. But don't expect much of an impressive gaming experience since the mouse does perform poorly at higher speeds. This is a concern for low CPI level players. We didn't experience performance lag while flicking as compared to the Cerberus, and we were able to aim and take down

enemies even at a low polling rate of 125 Hz. The Lite S is a great mouse at this price and in terms of accuracy, the 3509 sensor is definitely better than the Cerberus's A5050 sensor that loses tracking at high speeds. The cable attachment location is quite low on every MasterMouse but because of the S's textured cable, a noticeable amount of drag will hinder with your gameplay. This wasn't the case with the other two mice, where one of them has a braided cable whereas the other one has a flexible plastic cable. For the maximum advertised DPI of 7200, we found the maximum and true CPI to be around

CM MasterMouse Pro L

6600. The Pro L is the high-end mouse in their lineup, the focus being on using a close to perfect sensor, the 3360, and the ability to switch the body design between palm and claw grip with removable parts.

Gamdias Zeus P1 RGB

The Zeus P1 is the brightest RGB mouse we've had in our test labs and it surely looks brilliant. The RGB light ring reminds us of the Razer Mamba but here, there are two levels of the lighting around the mouse. The switches have low key travel and the feedback is great, making it our favourite for button spamming. The PTFE feet are too thin resulting in the middle-bottom portion of the mouse touching the mouse pad.

Gamdias Zeus P1 RGB

Hence, it suffered slight skips, leading to further inaccuracies. A hard plastic surface would be better rather than soft surfaces. The scroll wheel is placed noticeably higher and is highly responsive. The steady slope throughout the body makes it perfect for palm grip, although a groove at the right and left click would have been more comfortable.

Gigabyte XM300

The XM300 is another ergonomic mouse with ridges on both sides which makes holding the mouse quite comfortable. The CPI levels aren't true, so we had to recalibrate them for testing, ending up at 950, 1800 and 3600. White plastic surfaces take a toll on the mouse's ability to track, dropping smoothness drastically. The unit we had received skipped a step in the scroll wheel. This could either be a defective unit or it wears

GIGABYTE XM300

out sooner than expected. The 3988 is quite accurate and stable at higher speeds, and considering the price being under ₹3k makes it worthy of buying.

G.Skill MX780

While the MX780 does impress us with its alien-ish design, sturdy build quality and multiple lighting zones, it fails on sensor accuracy. In fact, in our testing, the MX780 won both on features and build quality, so kudos to G.Skill for picking the right features and materials. We found the advertised DPI levels to be inaccurate and had to calibrate them to attain true CPI levels before testing. The mouse functions the most accurate on a white plastic surface whereas the Avago 9800 laser sensor drops accuracy drastically

G.Skill MX780

on rough mouse pads like our Razer Goliathus Control edition. The CPI levels had to be recalibrated one more time just for the Goliathus mouse pad. Hence, if you're planning on getting this mouse, we would recommend you against using rough and soft mouse pads. The highest supported DPI level mentioned is 8200, but our CPI calculation came out to be around 7800 on a white plastic surface. The A9800 sensor suffers irregular acceleration, sometimes positive while sometimes negative. Apart from the sensor inaccuracy, the mouse comes with an exhaustive set of features in its software to customise the RGB light zones and easily assign macros, becoming the
