Gaming Mice

real world output on response time whenever the right or left click buttons were clicked. We used two different tools – KeyResponsePK and Human Benchmark. KeyResponsePK calculates the response time between two successive clicks (more accurate) whereas Human Benchmark calculates the average reaction time.

Acceleration was tested inside CS: GO and in MouseTester at different CPI levels. Any form of acceleration in the system and mouse software was disabled before testing. The age-old technique of shooting at a wall, swiping fast to the right and returning back to the original position was employed. In MouseTester, X and Y coordinates are also traced that can give us an idea whether there's acceleration.

To test angle snapping, we disabled it in the mouse's software (if available) and drew different shapes on MS Paint. Drawing also gives us an idea whether the sensor jitters at high CPI levels. The best way to determine whether prediction is implemented was to draw circles at different CPI levels, slowly and rapidly. On rapid circular motion, prediction can be easily detected where the curves of the circles form straight lines.

Features evaluation: The mice covered in this comparison are diverse – some are packed

with amazing features while some are plain and comfortable. Scoring has been kept objective based on whether a particular feature is present on the mouse or not. They aren't evaluated based on how well they perform since the implementation may vary among different manufacturers. For example, the procedure to change the RGB lighting modes on the mouse or its software won't be the same for two different manufacturers. Software capability has also been scored, and again, only based on available features and not ease of use. Outrageous features haven't been considered, only the ones that exist currently have been included. Things such as modularity to replace certain parts, a DPI profile switch button, extra teflon feet etc., have been added.

Build quality: To keep the scores objective, rather than scoring based on how good they felt, we've evaluated each mice considering the type of materials they use. We've tried to cover every part of the mouse in our calculation including the switches, cable and scroll wheel. The coating of a mouse is an important aspect to its build quality hence, we've further categorised the type of coating for various parts of the mouse. The touch and feel of the buttons, as well as the supported grips (palm or claw) haven't been considered because they are

subjective. Although these aspects will be highlighted in this comparison to make it easier for readers to understand more about the product, they don't affect the final scores.

Verdict: Essentially, the comparison will be concluded with three awards based on the final scores. The first one is Best Performer, which goes to the one with the highest score achieved in terms of sensor accuracy only. No other parameter related to other aspects are considered.

The Best Buy award goes to the mouse with the highest score/rupee ratio. In this case, the score will include sensor performance, along with the scores from features and build quality evaluation. This way, if a product happens to lack high-end features or build quality but has a lower MRP, the value for money score is automatically compensated. This is our way of maintaining fairness for the entry level mice in the comparison which don't have flashy features.

The final, Editor's Pick award is given based on the reviewer's favourite among all the mice. This could either be the Best Performer or Best Buy or some other mouse that was close in winning one of the two awards. The judgement is completely subjective, depending on daily usage and gaming experience of the reviewer.

of its useless location. But in the Ventus Z, the lower palm area sports the mesh that lets your palm breathe during intense gaming sessions. The Avago 9500 is more accurate on a solid coloured surface but the acceleration can be as frustrating as seen on the MX780. But if you're a high CPI player, you don't need to worry. The Ventus Z also acts

a great productivity mouse because of the extra buttons that can be assigned macros using the software. Few of the buttons have poor tactile feedback, but it's totally subjective on your part. The software does a great job of giving you granular control on what each key press will do, giving you a list of predefined actions.

Zowie FK2, EC2-A and ZA11

Zowie's lineup of mice are so exhaustive that no matter what size hands or grip preference you have, they'll surely have a variant for you. Players who love ambidextrous mice will feel at home with the FK2. It's built for gamers with smaller hands, but if you have bigger hands, the FK series

should be on your list. Out of the three that we considered in the comparison, we loved the ergonomic design of the EC2-A and how it perfectly took the shape of our hands. The maximum DPI is advertised as 3,200 but we verified from our MouseTester and Enotus tests, and found the true CPI to be around 3000. The ZA11 didn't have any CPI

difference as reported in the other two mice, and had close values out of the box. Because of the prominent bump at the middle, the extra height makes the mouse comfortable for palm grip users. All of them use the 3310H sensor which is highly accurate and have zero to negligible acceleration. But do note, the 3310H hates white surfaces and work best on black cloth mouse pads. Speaking of the differences, the FK and ZA series are ambidextrous and low-profile, while the EC series is ergonomic (right-handed users). If you're the kind of person who doesn't care about additional – and mostly useless features – but only care about comfort and accuracy in a mouse, Zowie has them all.
