Feature

Too fast, too furious?

when does high speed connectivity stop mattering?

Arjun Krishna Lal
feedback@digit.in

How fast, really, is too fast? With the impending rollout of Jio GigaFibre and the ongoing price war in the 4G space, the question is more relevant now than ever. Our analysis showed us that even with the rise of ever-faster connections, there are other tech issues regarding data delivery that are at play and need to be solved first. Besides, as with any technology of the past – be it 3D or 4K for example – the content is important too. Have you wondered just what do you plan on doing with a gigabit connection in the first place? Do you really need a gigabit connection to do the things you’ve always done? Probably not. But the answer isn’t that simple. Read on...

India's Digital Transformation

In the early 2000s, a digitally connected India would’ve been hard to conceive. Forget digital connectivity: providing reliable physical infrastructure—roads without the tar sliding off them and telephone networks that’d actually connect your calls—was often beyond the capacity of the state.

According to the TRAI, there are nearly 462 million internet users in the country, as of January. With everything from governance mechanisms to consumer entertainment products going digital, it’s important to not just look into the figures: More Indians are online today than the population of the United States. But how fast is their internet access? How reliable is it? And, most importantly, does it enable people to do what needs doing? If we’re here to talk about speed, it won’t be a

particularly interesting conversation: India continues to be ranked dead last in terms of average broadband speeds in the Asia-Pacific region. Going by an Akamai report, the average connection speed in India was 4.1 Mbps, as of Q3 last year. The year-on-year figures, however, paint a brighter picture: India registered among the highest rates of change. In 2014, average connections speeds were below 2 Mbps. Still, what does a 4.1 Mbps average actually mean in the here and now? Forget about latency, reliability, or even the fact that gentle wind can knock out your connection for hours in tier-II and tier-III cities (which has happened to us too many times to be dismissed as accidents). At the end of the day, you need at least a certain amount of bandwidth in order to even be able to do certain things. At all.
