

Root Checker is a good way to check if your phone has been successfully rooted

So is HTC's:

- Type "unlocktoken Unlock_code.bin" (without quotes), replacing "Unlock_code.bin" with the file you received.

For other devices, there is definitely a solution available even if your manufacturer does not sanction bootloader unlocking. Take a look at XDA Forums for the process for your phone. Complete the process, and you're another step closer to rooting your Android device.

FINALLY, ROOT IT

Now, there was a time when you would have to put a Custom recovery into your device and then grant superuser privileges to root your device. But now, things are much easier with quite a few third party applications available that take care of the rooting process for you. Some of the good ones are:

- CFRoot – Executable script in BAT file
- Baidu Root – Dedicated app via APK
- Towelroot – Dedicated app via APK
- Kingo Root – Dedicated app via APK as well as desktop app
- Kingroot – Dedicated app via APK as well as desktop app

Remember these are generic apps that may or may not work for your device. If you believe you have the skills and patience required, it makes much more sense to opt for a dedicated process for your device – something you

will be able to find on the device manufacturer forums or the XDA forums.

NOW WHAT?

If you're done with the rooting process, you're not done entirely yet. Due to the experimental nature of this process, it is best to verify that you've done everything correctly and you've still got a fully functional device with you. Root Checker is an application that will tell you immediately if you have Superuser permissions – which is a good indicator that your device is successfully rooted. Also, a root manager like SuperSU will be really helpful to control permissions in a rooted environment.

JUST IN CASE

Now, if you aren't exactly happy with the way your rooted device is working, or needed to go back to the unrooted state for any other reason, there are ways to do that too. Once again, make sure you backup everything first. Refer to the Backup section of this article to know methods applicable to a rooted device.

Once that is done, you can use apps like SuperSU or the third party rooting app that you used for the root process in the first place (most of the apps do have an un-rooting option). The most thorough method of doing this, however, is by flashing the stock firmware back onto the device. And just as you expected, this is not exactly an easy method.

- First, download the stock image and extract it.
- Then follow the same steps as the rooting process up to the point of OEM Unlocking.

- Copy boot.img and place it into ADB folder.
- Connect your phone to your computer, open command prompt and enter these commands:
adb reboot bootloader
fastboot flash boot boot.img
fastboot reboot

Pro-Tip: There are a few other methods to unroot as well, like deleting the files which grant the root in the first place, or unrooting with an OTA update, but these may not work for all devices. Flashing the stock firmware is the most likely to succeed.

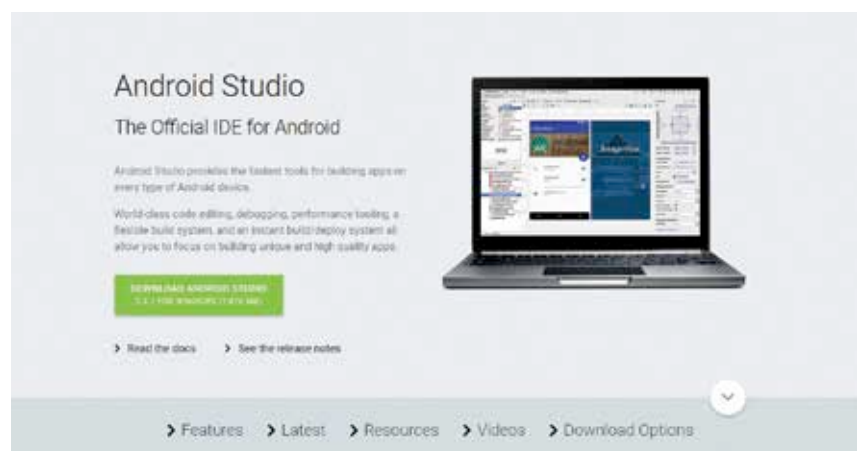

Up your Emoji game

If texting is your thing (if not, who are you?) then the emojis you use say a lot about you. Get your geek on by checking out these amazing apps, tips and secrets to using emojis like never before.

BUILD YOUR OWN ROM

It wouldn't be entirely wrong to say that Android would be nowhere close to its current popularity if it wasn't open source to begin with. Every component of the operating system – from the messaging apps, libraries, UI components and more – is available as code for free. It is because of this very flex-

Make sure you install the two packages mentioned earlier
