ment but actual security levels are far below what is indicated by this share. "Clients want to know if what they are spending on information security is equivalent to others in their industry, geography, and size of business in order to evaluate whether they are practicing due diligence in security and related programs," said Rob McMillan, research director at Gartner. "But general comparisons to generic industry averages don't tell you much about your state of security. You could be spending at the same level as your peer group, but you could be spending on the wrong things and be extremely vulnerable. Alternatively, you may be spending appropriately but have a different risk appetite from your peers," he said. And because of these incorrect assumptions, increased security budgets haven't resulted in greater security levels – a situation that has prompted many companies to sit up and take stock of their information security infrastructure.

This perception is gradually changing. Some clearly defined factors are emerging in the industry that have shown direct cost and effect benefits towards security:

- Establishing a workforce trained in the latest vulnerabilities and new threat avenues.
- Ensuring company-wide usage of encryption on each and every platform.
- Forming an incident response team that is well prepared to deal with a live breach.
- Cooperative participation in threat sharing with other companies.

New entry points

It has been a long standing practice to secure a computer with an anti-virus and a firewall. That practice has trickled down to a small portion of the smartphone community, with similar awareness regarding threats. Now, if you think that an individual smartphone is at risk, you couldn't be further from the truth. That level of targeting is quite rare and is mostly left to espionage novels and movies. What attackers do go after is your data,

stored at server level. And in the case of smartphones, a small margin of users actually check the permissions asked for by each app they install – thus the others grant access to their data even if it is not relevant to their use case.

On the other hand, newer data endpoints are emerging everyday. According to Gartner, Smart machines will enter mainstream adoption by 2021, with 30 percent adoption by large companies. These are machines that will make many decisions for

By nature, the IoT market is fragmented in terms of design and security. What does that mean? It means that there is no single security approach that applies to the entire connected devices market. Because of that reason, there is a high demand for cybersecurity professionals who can analyse and deal with cases specific to a certain company. And as the expenditure areas in the previous section showed, there is active effort to reduce the level of human error and system

Wearables are a new and unsecured entry point for attackers

themselves mostly while connected to networks. Even if they are not entirely autonomous, security for these has to be implemented differently.

Last year, the Mirai botnet attack demonstrated the potential of IoT security breaches. IoT indeed is something that has been discussed a lot from a security standpoint, but then again, it is the Internet of 'things' – anything new that is connected to the internet falls under IoT. And anything connected to the internet is vulnerable. Cars have been hacked, a popular U.S. smart home alarm system was hacked, implantable medical devices like pacemakers have been hacked, plane systems have been hacked, critical infrastructures like a power grid and a dam were hacked, mobile banking apps have been hacked, smart city technology has been hacked, and even a traffic management system has been hacked in Washington, D.C.

glitches possible, making CyberSecurity a lucrative career opportunity right now.

What can you do

It is true that cybersecurity, as a career choice, has always had a steady demand - till now. In the coming few years, as factors above indicate, the demand is not only going to grow - it is going to widen as well. According to Glassdoor, an entry level Information Security Analyst can make upto 8lpa, and it only goes higher from there.

Building expertise in new and emerging platforms, which have their own vulnerabilities, is a good first step towards a career in this growing market. Also, developing practical experience alongside that can never be a bad thing. For anything beyond that, stay tuned to this space for a detailed article on building a career in cybersecurity next month.
