

3D printed working ovaries

Using tissue as ink, scientists successfully 3D printed mouse ovaries that can actually grow mouse pups. <http://dgit.in/Ovary3D>

Dubai unveils robot police

Dubai unveils the world's first operational robot policeman that can detect gestures and use facial recognition. <http://dgit.in/roboCop>

here, you can fit in way more tracks on a single disc, leading up to a storage of 360 TB per disc. For comparison, the largest single HDD you can buy is 12 TB WD Helium and for an SSD it is a 60TB monster that Samsung recently showcased (which is also expected to cost about \$30k per piece so there's that). With the remarkable physical strength and anti-corrosiveness, the data can theoretically last several billion years if stored carefully. The bad news? While the hardware to read 5D storage is already (sort of) available commercially (albeit very expensive), the lasers to write it aren't going to be making an appearance anywhere else beyond the labs for a while yet.

03 "SHINE ONNN ME CRAZY DIAMOND"

If you have ever secretly wanted Elvis Presley's rhinestone studded jumpsuit, here is your chance. Even better, it's made out of diamonds so you can pull a suave "Diamonds are a girl's best friend, no?" pick up line (We kid, we kid, please don't do this). A carbon chemist named Dr Haifei Zhan from the Queensland University of Technology, Australia is working on incorporating diamond nanotubes (Basically, a line or tube of carbon that is one atom thick that mimics diamond's structure, that is incredibly strong, light AND flexible) into more fabrication and manufacturing as well as everyday usage. To know more about his research go to <http://dgit.in/DmndThrd>. He hopes that one day, "DNT may become as ubiquitous as plastic". He also says due to its much-increased flexibility over its plebian carbon nanotube cousin, you can incorporate it into clothing, from bulletproof vests to rugged, working gear. Maybe even diamond jeans. How cool would that be?

04 ADVANCED INDEPENDENT TOOTHBRUSHES THAT DON'T NEED NO TOOTHPASTE

What will the Japanese ever come up with next? Time and time again,

they've proven they are ahead of the world's meta curve (Seriously, look at their Kit Kat flavours) And toothbrushes... toothbrush? Something. That don't need toothpaste. The admittedly cool looking transparent brushes need to be just dipped into water to work. The bristles are specially tapered and there are some mineral ions bonded there using some nanotechnological jujitsu so when you brush, you don't hurt your enamel but get all the plaque, detritus and other icky things out and the minerals pass onto your teeth, making them stronger and whiter. Here's where to buy them: <http://dgit.in/MskaTBrush>. You know you want to ;) Is #YellowTeethMatter a thing yet? LOOK SJWs, ANOTHER OPPORTUNITY.

05 GRAPHENE, THE MIRACLE MATERIAL

Ah, the science world's wonder kid, Graphene. Who knew a single layer of carbon atoms attached in a hexagonal manner would be able to do so much? Adding to the list of absolutely amazing properties Graphene already has: Let's see, one of the thinnest materials known to man (it's pretty hard beating that 1 atom thickness), one of the lightest, one of the strongest (100-300 times stronger than steel!), one of the best heat conductors at room temperature, one of the best electricity conductors ever. All these make it the perfect candidate for making flexible electronics, making quantum bit computers and a whole host of other functions (phew). In fact, it has been recently found out that a graphene sieve can make seawater drinkable. This is huge for underdeveloped countries who are struggling for clean, potable water but can't afford the expensive desalination plants. There can be LifeStraw-esque products that can be easily distributed to people to make water scarcity a thing of the past. Overall, graphene is essentially the swiss knife of scientific inventions.

06 BOROPHENE> GRAPHENE?

Or "Yes, we're going to bash on something just after we praised it" While graphene is wonderfully amazing, it's still helluva a lot of expensive. To give you a perspective, a micrometre flake of gold costs about \$0.0004 while the same amount of graphene costs over \$1000! Even though you need relatively less amount of graphene to do anything compared to conventional materials, it's still pretty expensive to procure pure graphene from graphite. Borophene is a proposed alternative that shares pretty much all the same functionalities and properties of graphene (it might even be a better conductor of electricity) and more importantly, would be easier and cheaper to upscale production than graphene. There are a few minor trade-offs though, so scientists still have to economize graphene production as a first priority. But now we have a viable alternative in Borophene. Or should we say "Brophene"? No? Ok we'll show ourselves out :(

07 VOYEUR INTO THE SECRETS OF THE CHEMICAL BOND

Nothing is safe from the prying eyes of Science. Researchers have found out that they can focus light down to a size smaller than its wavelength (here before thought impossible) using a quirk gold atoms exhibit to create the world's smallest magnifying glass. They made a bump in the highly

Vantablack: Indian Censor Board is itching to get their paws on this
