

The Sennheiser HE1

Costing just Rs. 45,00,000, the Sennheiser HE1 is the world's most expensive headphone paired with a tube amp.

Twitter warns Vine users

Mass email to Vine users states that their email addresses and phone numbers were exposed.
<http://digit.in/vineMail>

conductive gold nanoparticles (Gold is one of the best metal conductors in the world) to use as an optical cavity that can hold only one molecule. This optical cavity focuses light to less than one billionth of a meter, allowing us to image the actual chemical bonds and other inter and intramolecular reactions in never before seen detail. Here is a more detailed explanation: <http://digit.in/Magnif>. This opens up various avenues to studying why exactly anything happens and could lead to several new discoveries in materials and effects. Like making optomechanical harddrives which store data as light vibrations. WHOA!

08 VANTABLACK DETHRONED

You would've undoubtedly heard about the World's Blackest Black, a black so black that when you photograph it, it looks like it was Photoshop censored. And of course, the licensing squabble that happened after it and the tiff between several artists. If you haven't, let us break it down for you - Scientists made a material so black that it absorbed 99.965% of light radiation. They made it of Vertically Aligned NanoTube Arrays so they called it Vantablack. How ...creative. Light usually reflects off a surface when it strikes it but in this, it becomes trapped in the forest of nanotubes and just continuously bounces off them until it dissipates into heat. Then a scandal happened when the artist Anish Kapoor's studio was given exclusive rights to use the color and the artistic world grew outraged at this blatant discrimination (so much that another artist Stuart Semple created the World's Pinkest Pink and made it available to everyone but Kapoor which then Kapoor got his hands on and Semple was hurt so he made more exclusive colors like the world's glitteriest glitter, greenest green, yellowest yellow... we digress. Beg your pardon) Well, as it turns out, there need not have been this much fuss. Scientists have recently discovered Vantablack

2.0, which is so black that not even lasers reflect off of it and spectrometers can't even analyse it and it is safer and easier to use too! Ninja Assassins are just gonna get even better now... great. Not to mention censor boards.

09 QUANTUM COMPUTING SAY WHAAA

Okay, so this is a bit tough to get heads wrapped around so bear with us. So point number one, Computers are being used nearly in every facet of our lives right now and the numbers just keep on going. In a few decades, at this current growth rate, we'll have to supply more power to computers than what we can produce. This, obviously, is impossible. Increasing power efficiencies of computers and increasing

This has to be the most badass looking internals of a missile ever

production of electricity is just postponing the inevitable. Point number two, a scientist called Rolf Landauer from IBM found that to process any one single bit of information in any computer, a minimum amount of energy must be used. Our computers right now, even the most energy efficient ones use up power several orders of magnitude higher than this minimum amount. Point number three, binary systems use two states 1 and 0 to store information. This severely limits the amount of data you can store and process because effectively, all you can communicate is on and off to the processor. So, quantum computers, to put it very simply use "quantum-mechanical phenomena" or the interaction of

several sub-atomic particles to carry out computational processing. It also has two states called qubits (Quantum Bits, get it?) but instead of it just storing the on or off values, it can hold a whole lot more of information based on its position within the atom. If that didn't confuse you enough, here's the more scientific version: <http://digit.in/QntmComp>. And since it doesn't take much energy to move these subatomic particles around, it comes within the minimum amount of energy for processing, thereby creating incredibly powerful systems that take very little power to run. Scientists have now gotten much closer to this vision with several discoveries lately. For instance, using extremely small pulses of light to move electrons in a semiconductor and figuring out how gravity affects these particles. This would be based on a similarity noticed between a black hole's entropy and extremely cold helium atoms.

10 TARGETED MEDICINE NANO MISSILES

Nanotechnology is also used in the field of medicine to create custom drugs that are more effective, safer and are overall better. Recent developments have created smart materials which are injected together with the drugs. They help deliver the drug to the target site quickly and without much attenuation of potency, thereby reducing the doses needed. These materials (it changes depending on what kind of drug you want to inject with it and the target site) also prevent the drug from interacting with other cells and thus reducing the risk of side effects. Researchers are also looking at using nanotechnology to deliver the drugs deep inside cancerous tumours to effectively destroy it from within, which should give better success rates than chemotherapy without the risks or limitations of surgery. Oh, and if you ask us, they should totally name this process as "Blowing up the Death Star" when they explain this to the patients - for the smiles. 🇮🇳
