

Windows 10 China edition

Windows 10 China Government Edition announced, will let officials control encryption and telemetry. <http://dgit.in/Win10China>

AMD's new Threadripper

The Threadripper will be the first consumer-grade desktop chip with 16 cores and 32 threads. <http://dgit.in/threadripper>

tural ties exist with the Urals, with the Mediterranean area and Iran. Possibly, the Dravidian-speaking people established themselves in northwestern India during the fourth millennium B.C.E. While traversing to India, the immigrants may have chanced upon the Ural-Altaic speakers, which would explain the commonality.

It is widely believed that the Dravidian languages were brought to India by people from the ancient city of Elam, which was situated in modern-day Iran. Scientists have also found mtDNA traces in some Indians connected to the Western Eurasians

Asko Parpola, who believes the Harappans were Dravidian, notes that Mehargarh (7000 BCE to c. 2500 BCE), to the west of the Indus River valley, is a precursor of the Indus Valley Civilization. Mehargarh's inhabitants migrated into the Indus Valley and led to the formation of the Indus Valley Civilization. However, perhaps the most widely accepted theory of migration in India is regarding the arrival of the Indo-Aryans.

The first Indo-Aryan wave went over the Hindu Kush

INDO-ARYAN MIGRATION

The Indo-Aryan migration theory proposes migrations from the Sintashta culture through Bactria-Margiana Culture and into the northern Indian subcontinent, which led to the onset of Indo-Aryan languages in India. Based on similarities between northern Indian and western European languages, it's also supported by archaeological and anthropological research.

The theory – proposed by scholar Max Mueller – asserts that these

Indo-Aryan speaking people may have been a genetically diverse group of people who were united by shared cultural norms and language, referred to as “noble” or Arya. Diffusion of this culture and language took place by patron-client systems, which allowed for the absorption of other groups into this culture, and explains the strong influence on other cultures.

The standard model for the entry of the Indo-European languages into India suggests that the first wave went over the Hindu Kush. It formed the Gandhara grave (or Swat) culture, either into the headwaters of the Indus or the Ganges (probably both).

The concept of an Indo-Aryan immigration was first conceived in the 18th century when it was discovered that the Western and Indian languages bore a striking similarity. The Proto-Indo-Iranians, from which the Indo-Aryans developed, are identified with the Sintashta culture (2100–1800 BCE), and the Andronovo culture, which flourished around 1800–1400 BCE in the steppes around the Aral sea, present-day Kazakhstan, Uzbekistan and Turkmenistan.

It is believed that the Bactria-Margiana Culture greatly influenced the proto-Indo-Iranians. It is from them that they internalised and borrowed distinctive religious beliefs and practices. The Indo-Aryans allegedly split off around 1800–1600 BCE from the Iranians, after which they migrated to the Levant and north-western India.

However, new research has questioned this theory and asserts that “there was no genetic influx 3,500 years ago.” Researchers state that Indians are not descendants of Aryans.

WHAT NEW GENETIC RESEARCH REVEALS

Through genetic testing of present-day Indians, researchers from the University of Huddersfield were able to ascertain from where Indians originated.

The researchers reveal that some genetic lineages in South Asia are very ancient. The earliest populations were

hunter-gatherers who arrived from Africa (where modern humans arose) more than 50,000 years ago. But with the spread of early farming, further waves of settlement came from Iran, after the last Ice Age ended 10, 000 to 20,000 years ago.

A mid-Victorian map of India

This assertion is in line with the previous findings. The earliest settlers from Africa were likely the ones who arrived on the Indian Subcontinent after the Toba eruption. The settlers from the Iranian side were most probably the Dravidian people.

Most of the genetic research data was based on the mtDNA (Mitochondrial DNA), which tracks the female line of descent. On the other hand, the male line is tracked by Y-chromosome alterations – and these are quite different. The genetic testing reveals that major signatures in the male line are much more recent. Most controversially, there is a strong signal of immigration from Central Asia, which is less than 5,000 years ago. This signal likely ties into the arrival of the Indo-Europeans or the Indo-Aryans.

Thus, it is clear how Indians have derived their culture from different traditions around the world. The country owes its rich cultural heritage to those who migrated from distant lands thousands of years ago.
