

Entergy unaffected by Trump

CEO of Entergy says that despite Trump pulling out of the Paris agreement, the company will stay the sustainable course <http://digit.in/TrumpedNot>

Apple car in the making?

Tim Cook says that Apple will focus on autonomous automobiles and calls electric driving a marvellous experience <http://digit.in/Appledrive>

Let's mine Ethereum

Mining cryptocurrency with your graphics card is profitable once again.

Mithun Mohandas | mithun@digit.in

C

ryptocurrency is hot and happening all over again. Except this time, it isn't Bitcoin. Oh no,

mining Bitcoin is beyond the tools that the ordinary human can get his hands on. Ethereum, a new cryptocurrency is all the craze now and it's rising in value fast, ridiculously fast. Mining Ethereum is still possible for you and me, and all you need are a couple of GPUs and a few software that we're about to get into.

GET YOURSELF A WALLET

Almost all miner software have a manner of creating a new wallet address within the interface or you can try using a GUI tool website such as MyEtherWallet. The process is fairly simple, you enter a password (choose wisely, this cannot be altered later on) and the service allows you to download a Keystore file. This file along with the password will allow anyone complete control over your wallet so protect it with utmost care.

POOL MINING

Mining solo isn't advisable since the payout only happens once you mine an entire coin. The difficulty is always rising, and the time taken to mine one coin solo is pretty high with just one graphics card. Mining in a pool is like digging a ditch as part of a chain-gang. The job gets done quicker.

Now, there are plenty of mining pools out there. Some require registration and some don't. Alperium is a good wallet to start with since it has a low commission rate of 0.2% on all of the pools that it controls and the minimum payout is 0.2 BTC with a window of 30 minutes. Once you visit their website, you can find servers and configurations listed. The configuration consists of three main parameters: Stratum Host, Standard Port, VARDIFF Port and Redundancy hosts (optional). Once you've obtained these, you'll need a mining software.

HARDWARE

You'll obviously need a powerful graphics card to turn a profit. We're running a GTX 980 Ti on a Windows 10 machine. An aftermarket GTX 980 Ti can run easily on a 500W PSU. We'll be using an 800W PSU because the mining operation will be running round the clock and getting a PSU rated roughly twice your required power should give you maximum efficiency. You'll also need to worry about cooling if you are planning on using multiple graphics cards. For a comparative analysis on which graphics card is the best for mining ethereum check this link out (<http://digit.in/EthHrdwr>).

MINERS

If you have an AMD graphics card then Claymore is a very good mining software, on the other hand if you have an NVIDIA graphics card then ethminer has improved CUDA support to make the most of your hardware. Do note that all miners support CUDA and OpenCL so you can use anything under the sun. If you'd like something a little more simple with a GUI then check out Awesome Miner. For this DIY, we will be sticking to the plain old command prompt with Claymore.

Once you have the card installed, you should check the GitHub readme

for the mining software to see which drivers they recommend for the latest version. We used version 9.5.

Once you have Claymore installed, open a command prompt and navigate to the install directory. Remember the Address you generated upon wallet creation? And the miner configuration from Alperium? You'll need that information now. We chose the Asian pool so our Stratum Host is asia.alperium.ch and the port is 3002. For this example, we're going to assume the address to be 0xd84756ANGHRC84755687432568250945f1993308 and we'll call our worker Humphrey.

You also need to set environment variables based on your GPU and the following should be sufficient:

```
setx GPU_FORCE_64BIT_PTR 0
setx GPU_MAX_HEAP_SIZE 100
setx GPU_USE_SYNC_OBJECTS 1
setx GPU_MAX_ALLOC_PERCENT 100
setx GPU_SINGLE_ALLOC_PERCENT 100
```

Just type out each line in command prompt and press enter. Move over to the command prompt type the following to initiate mining:

```
EthDcrMiner64.exe -epool
asia.alperium.ch:3002 -ewal
0xd242CAA7B9AC1f-
c08912695891250945f1993308.
Humphrey -epsw x -mode 1
-ftime 10
```

The above command is a bunch of flags followed by configuration parameters. You can figure out what other parameters there are and what they mean over here (<http://digit.in/Clymr>). For now, the above mentioned ones are enough for our needs. If you need a more more details, head over to geek.digit.in for a longer guide. We've also included a few mining tools for Ethereum, so don't miss them out.

That's it. Your GPU should start crunching away and earning your Ethereum which should soon make you filthy rich.
