

SpaceX does it again

This is the 2nd time the company has launched and landed a recycled Falcon-9 rocket successfully. <http://digit.in/F9SpaceX2>

Deeplearning.ai after Baidu

Andrew Ng, formerly the chief scientist at Baidu has announced his next venture - Deeplearning.ai with an August launch <http://digit.in/Deeplearnai>

Of Pigs and Men

Ayushi is a successful working professional with loving family and friends who is perfectly healthy and fit – until she wakes up one day with some pain in her chest

Prithvi Sudhan | feedback@digit.in

S

he is rushed to the hospital, where doctors come to a dismayed diagnosis: A weakened heart

valve. Unless Ayushi gets a heart transplant, her days are numbered. Luckily a match on the donor registry is found and miraculously, she manages to receive a matching heart transplant promptly, and makes a full recovery. A few weeks of rest and she was able to continue on with her life like nothing had happened. If only everyone else were this lucky...

In India, there is a demand for more than 175,000 kidneys, 50,000 hearts and 50,000 livers every year with approximately 500,000 people dying because of the lack of available organs for transplantation. They wait with bated breath, hoping against all odds that somewhere, a matching organ is found. More often than not, they are disappointed. So they turn to the black market – India has one of the largest illegal organ marketplaces in the world, with unsavoury elements abducting people to forcibly harvest their organs, and debt ridden people selling their kidneys for money. And it still manages not to be enough. So many lives lost, most of them preventable, only if there were some

organs at hand... Well, people may soon not have to rely on donors that much anymore – For scientists may just have figured out how to grow fully functional human organs, INSIDE another animal.

CHIMERAS ARE REAL!

Obviously, in this case, not every animal would work (flashback to 6th grade Biology – “THE HUMAN HEART IS THE SIZE OF A CLENCHED FIST”. Try imagining a clenched human fist inside a mouse. Yeah).

The animal has to be of a sufficient enough size and its naturally occurring organs must be sort of similar to our own – for example, a pig or a cow. Scientists manipulate and inject *pluripotent cells* (or cells which can develop any kind of tissue) of the patient into the *blastocyst* (one of the early stages of an organism's development after a zygote has been formed – blastocysts mark the phase when cells start dividing into different specialised roles which will then develop into different organs). The manipulation,
