

SHOWCASE

Xbox One X

Let's start this showcase off Microsoft's latest beast of a console. That's right, we're talking about the Xbox One X which was officially revealed at E3 this year. We knew it was coming for a while now and we even got to see the specs on this baby a few weeks prior to the official reveal. Microsoft promises that the Xbox One X will be the most powerful console ever. We're inclined to agree with them after

looking at that juicy spec sheet. The Xbox One X, like the Xbox One S, will support UHD 4K gaming but unlike the One S which simply scaled games up to 4K, the Xbox One X will be powerful enough to run games at 4K natively. Additionally, since most games don't really run at UHD natively, many games will be getting special Xbox One X treatment to make full use of the console's powerful specs. Look out for Xbox One X launch special games which will most likely release with 4K support. The Xbox One X is expected to release on November 7 2017. I wonder what they'll shorten this down to, XboneX? Xbox X? XoX? Ah, whatever. We'll let you know when one sticks.

Safecast bGeigie Raku

The bGeigie Raku is a radiation device with GPS and data-logging enabled which arrives in a kit and is supposed to be assembled together. It's a part of the Safecast network. Safecast is a sensor network and is present throughout the world. Born due to the 3/11 Fukushima disaster exposing the complete lack of radiation data in the world, their goal is to collect and publish the readings to make it publicly available.

The whole set with the Arduino and open hardware neatly comes in a Bento box with a Geiger system since the volunteers preferred something concise and compact. Accurate readings worldwide could be used with other medical data to meaningfully interpret many a phenomena which in turn could potentially save lives in the future. By using the CCO public domain, it is available to everybody.

The bGeigie Nano houses a pre-assembled main board that comes with plug/snap components which eliminates the need for soldering (like in previous models). The upgraded version comes with more processing power complemented by a bigger and better screen combined with onboard Bluetooth to allow measurement uploads through both Android and iOS. Along with being easy to hack and with a faster CPU, it incorporates more memory while remaining Arduino-compatible throughout. No editing configurations files are needed as it comes with a joystick controller. The devices have been professionally tested in labs in Japan, Germany and the US. It won the Good Design award in 2013.

Microsoft Modern Keyboard

The new Modern Keyboard is Microsoft's successor to the Surface Keyboard, which is obvious just from looking at the Modern Keyboard. Actually they're similar in just about every aspect except the Modern Keyboard comes with a fingerprint reader built into it. Additionally, you can use a cable to use the keyboard with a wired connection with your device as opposed to a wireless one;

which the Surface Keyboard was limited to. The fingerprint reader can be found in the second Windows key preset on the right hand side of the space bar. You can use it like you would a fingerprint

reader for your smartphones to instantly log into Windows and even websites. The Modern Keyboard will be compatible with Windows 10, MacOS, and Android. The keyboard is expected to launch priced at \$130 (₹8,400/- approx), which is about \$30 more than the Surface Keyboard which isn't really all that old. So if you recently purchased a Surface Keyboard, hard luck my friend. It happens.
