

SCIENCE IS THE PATH TO KNOWLEDGE, AND FINDING OUT ABOUT HOW OUR UNIVERSE WORKS. YOU CAN'T BE A GEEK AND NOT KNOW YOUR SCIENCE!

FUTURE PLANS

HOLD ON TO YOUR SEATS AS WE START OFF THIS TIME by exploring the truth behind quantum teleportation and how close we are to actually achieving it at a level that matters. And if you were thinking we're all about such cool stuff, move on to the next piece about eating insects for dinner. Yes, you read that right. Maybe someday that's all we'll have left to eat, especially when we get to Mars in the next story?

The rise of frogs

A new study has found that majority of the extant, or existing frog species (approximately 88%) on our planet expanded after the catastrophic event that wiped out the dinosaurs 65 million years ago.

WHAT'S NEW

Biosensing tattoo ink

Researchers from MIT are developing a biosensing, color changing tattoo ink known as Dermal Abyss that can change its color in response to variations in interstitial fluid present in the body.

The pH sensing ink changes from pink to purple depending on the alkalinity of interstitial fluids and a glucose sensor changes from blue to brown as the concentration of sugar increases. Another pH sensor glows at a higher intensity under UV light as salt level increased on the skin. Thus, users can easily monitor the colour changes and the need for insulin.

With this new technology, researchers hope that maybe one day it can help diabetics monitor

their glucose levels more easily and replace the current painful procedure of piercing their skin 3 to 10 times per day.

Teleportation IRL

In an attempt to create a global-scale quantum internet, a team of researchers from China was successful in teleporting a photon from Earth to a satellite in orbit around the planet. This experiment becomes the first satellite-to-ground quantum network ever created. Based on quantum entanglement, the scientists broke the record for the longest distance (500 km) over which entanglement was achieved previously.

Teleportation has already been carried out several times in labs but only photons were teleported to distances over 100 kilometres. These instances were conducted using optical

fibres or terrestrial free-space channels. Because of photon loss through these mediums while traversal, achieving longer distances was limited. Establishing entanglement between a set or group of photons and teleporting all their properties hasn't been achieved yet. So, we have only been successful in teleporting single photons over short distances and are way too far from teleporting ourselves.

Analysing a missile's capability

You don't have to be an analyst at the CIA or the MI6 or any other three letter agency to figure out the acceleration and capabilities every time North Korea fires a missile. All you need is a small video analysis tool and some physics know-how.

Post-Ebola syndrome

A new study suggests, Ebola may still not be done; it might have just shifted to a clever stealth mode. From examining archived tissue samples from infected monkeys, researchers found out that the virus could create a reservoir in certain immune cells and hide under the body.

Planet of the Ravens

A series of experiments conducted on a few hand-raised ravens to study the outer bounds of their cognitive abilities found out that these birds were able to plan ahead and might be more intelligent than we actually thought.
