

Capital Float raises \$45M

Online platform Capital Float raises a \$45 million Series C led by Ribbit Capital. Learn more about the news here: <http://dgit.in/CapitalFloat>

Video support on LinkedIn

LinkedIn is rolling out a new update that will allow users to upload videos to the social network. <http://dgit.in/LinkedInV>

to manage and most importantly more child friendly in every feasible way.

The solution consists of a custom glucose meter that uses NFC or Bluetooth to transmit data to a mobile application, which in turn is connected to a cloud based application running on Microsoft Azure platform, that processes the data in real time and uses AI to offer advice and monitoring. The custom glucose meter itself is the thinnest ever in the world that uses no buttons or display, making it a lot cheaper to mass produce and child friendly at the same time. What impressed us the most was how the team realized an opportunity to use technology to solve a global problem - the need for a child friendly glucose monitoring system. Given that there has been absolutely no real change in the way glucose is measured since past several years, while diabetes cases amongst children, unfortunately, have been rising steadily across the globe. As winners of Imagine Cup 2017, team X.GLU bagged a mentoring session with Microsoft CEO Satya Nadella, \$100,000 in cash, a \$125,000 Azure grant and a trip to the Microsoft Build developer conference next year.

Team Oculogx from Georgia Tech university in United States took the second spot with their mixed reality based solution that uses Microsoft's HoloLens and Microsoft Azure cloud services to improve the efficiency of work force when it comes to order picking in large warehouse. Oculogx's Pick AR solution integrates navigation, barcode scanning, and direct communication with warehouse management software systems to improve overall efficiency. A warehouse worker is directed to the exact location of the item using overlay navigation via the HoloLens. Once picked, the application software also reads the item barcode and communicates the information to the warehouse servers and order management system. The integrated barcode scanner prevents the worker from picking the wrong item as well. The solution, as you might have guessed, is to a considerable extent, tailor made for

THE INDIAN CONTINGENT

• **Team 3alchemists from Medicaps Indore:** 3alchemists developed a cost-effective solution for early detection of Alzheimer's disease. The solution is based on an application that not only offers tests for detecting the disease but also helps monitoring and treatment of Alzheimer's patients. What impressed us the most was the "Musicia" feature in the app. The feature generates a specific tone that uses neural network system based API to positively impact certain parts of the human brain that might be impacted due to Alzheimer's disease.

• **Team Negative Time from BITS Pilani:** Content Holmes, developed by Team Negative, is a solution that protects children from cyberbullying, depression and internet addiction. Content Holmes uses a filtration layer to protect children

Team Negative Time from BITS Pilani presenting to the judges for a spot in the semifinals.

from abusive language as well as pornographic sites by blocking and altering content at the final layer. The app also has monitoring features, for instance, a mood analyser module keeps track of child's behaviour and sends alerts to parents about any abnormal behaviour that might indicate depression or any sort of addiction. Unlike existing products in the market, that can be bypassed using virtual private

networks, Content Holmes alters content at the final layer, and hence cannot be circumvented via the VPN route. Yes, Content Holmes is likely to face a lot of heat around privacy and internet censorship concerns.

• **Team PocketConfident AI from IIT Hyderabad:** PocketConfident AI offers the first virtual coach powered by Artificial Intelligence. The solution is based on a self-learning model that helps individuals with daily challenges of life though a virtual coach of sorts that helps bring clarity in thought and builds confidence. Essentially, the PocketConfident will ask you a bunch of questions when queried. With each answer, the AI tries to learn more about you and the problem you are facing. The final motive is to build a clear logical path that might help you solve any dilemma or confusion that could be preventing you from arriving on a clear decision. While it does seem like PocketConfident AI is trying to be your 'always available' therapist that runs on AI, the team clarified otherwise. In fact, it is marketed as a solution to situations when one cannot access human support because of time of day, cost, stigma, or privacy issues.

the US market. And, as you'd probably also know, the Microsoft HoloLens doesn't come cheap. Having said that, what makes Pick AR noteworthy is the fact that it uses mixed reality to simplify and bring efficiency for a wide array of businesses.

The third spot went to team Nash from Argentina. Team Nash created ResCue, a solution that uses a network of imaging capable drones to shorten the response time when tackling natural disasters. Each drone is paired with a Raspberry Pie that runs a JavaScript based app that uploads images of

disaster struck areas to an Azure based cloud platform on real time basis. The Argentinian team's solution was primarily tuned towards tackling floods situations, where timely location of stranded victims and speed of response becomes critical. The concept of saving lives by using the combination of drones and cloud connected services to locate disaster struck areas does seem viable. Especially in our country where floods are a common occurrence. However, the speed of response after locating the victims is perhaps as critical as locating the problem itself. 📌
