

Andromeda shuts down updates

Bioware releases a statement stating that the company is officially shutting down updates for all single-player content. <http://dgit.in/updateAndro>

World War II warship discovered

The USS Indianapolis that sank during WWII when a Japanese submarine struck it, was discovered 18,000 feet below the Pacific. <http://dgit.in/USSship>

contains the files that are required for your generator to run. Yeoman also creates some required files such as .editorconfig, .eslintignore, etc.

Now if you view the package.json (<http://dgit.in/PckgJSON>) file, you will find that the Yeoman generator has created some other files – some dependencies and devDependencies.

First coming to the dependencies, you can see a basic package Yeoman-generator has been added. That package is basically the heart of the project. Every generator must have this package as a dependency.

Other two packages are **chalk** and **yosay**. **chalk** is a package that helps to colorize the text in the console. Because Yeoman is a CLI-based application, you're going to want to enhance the user experience by colorizing it. **yosay** adds some cool things to your CLI. For example, you can get it to do something like **cowsay**, but without the stupid cows!

For example:

```
const yosay =
require('yosay');
const chalk =
require('chalk');
console.log(`Hello ${chalk.
red.underline(process.
env.USER)}. This is a test
string.`);
```

Will generate an output as shown below:

SET UP THE TEMPLATE FOLDER

Now, coming to the project your goal is to create a simple application, such as a basic express application. You will need a javascript file that is basically the backend as well as a frontend file that will be communicating with the javascript app.

The file structure is very simple. The first step is to make sure all the required

files exist in the project's directory or are created in the template directory. So we create the required files and folders accordingly. So after creation of the template files and folder the template folder should look like this:

```
class extends Generator {
  paths() {
    this.sourceRoot();
    // returns './templates'

    this.templatePath('index.js');
    // returns './templates/index.js'
  }
};
```

Next, you need to add some code into the app.js and view.html. Remember that these code snippets are going to be copied to the destination path where someone will eventually generate the sample project. Our suggestion is to make it as readable as possible right in the beginning, and to add comments whenever possible, to give the person working with your code an idea of how and why things are working.

Get sample code for app.js here: <http://dgit.in/SampleCde>.

If you look at line 38 and 39, we are using the EJS Template syntax to inject values – more on that later.

Here's a sample of the view.html: <http://dgit.in/ViewHTML>.

Now that you're ready with your basic template files, you can move on to the bit where you need to take user inputs depending on your requirements, and scaffold the project accordingly.

CODING THE GENERATOR

In any generator, the main file resides at index.js within the generators folder.

If you look inside the file, you will see a class that is extending the class Generator that came from the yeoman-generator package. If you are new to the concept of extending in JS, you need to read up on that now.

THE YEOMAN RUN-LOOP

There are some methods that are defined within the class. Any genera-

*CODING MATTERS

*Microsoft Introduces CoCo Blockchain Framework

Microsoft has developed a blockchain framework that uses Intel technology to bring the protocol more widely into business use.
