

The brain is our most complex organ, yet we are still struggling to truly understand how it functions! Shown in these images is what we do know

What about brain dead individuals? What about people who have suffered from a stroke? People who are totally paralysed in body, but still healthy in mind? What about the opposite, with people who suffer from Alzheimer's slowly losing all sense of self, despite keeping relatively healthy bodies?

Needless to say, it's obvious that the consciousness is tied into the brain intrinsically, and we know quite a lot more about the brain than we did before. We know which parts of the brain do what (roughly) and know in which parts what kind of "processing" occurs. We know certain parts of the brain are so important that slight damage renders us vegetables for life, or can kill us. Whatever the case, there's no doubt that the concept of "consciousness" is so heavily dependent on the body, that it cannot be something that's abstract and external of the body, or independent of it.

EVOLUTIONARY NEURODYNAMICS

The idea of this new field of study is that equates how the brain functions to evolution... no, it's not just saying that evolution is responsible for our brain... because that would be stating the obvious. What this field is suggesting is that natural selection occurs in your brain on a daily basis!

The field proposes that inside your brain, there are replicators which, well, are a lot like individuals reproducing. However, it also says that there is natural selection happening, constantly, and thus ideas are being selected based on their fitness. An overtly simplistic way of understanding this, is to look at how the brain
