

Mobile C50 Flash Drive

Late in July, Silicon Power announced a unique series of USB flash drives which they're dubbing the Mobile C50. The Mobile C50 is, for the lack of a better word, the swiss-knife of USB drives. Why you ask? Well because one drive features all three types of major USB connectors.

The C50 series is equipped with a USB Type-A connector, a USB Micro-B connector and a USB Type-C connector and will come in 32GB, 64GB and 128GB variants.

The unique design features the Micro-B connector inside the Type-A connector which can be snapped open. Meanwhile, the Type-C connector is on the other end of the drive

and is protected by a rubber cover. Additionally, the drives are quite rugged, touting resistance against water, dust and vibration and also being operable at temperatures between 0 to 70 degrees Celsius.

The USB Type-A and Type-C offer USB 3.0 transfer speeds of upto 5 Gbps, while the USB Micro-B offers USB 2.0 speeds and can hit transfer speeds of upto 480 Mbps.

USB 3.2

We've already got USB 3.1 which is capable of transferring data at speeds of up to 10 gigabits per second. But that's not enough. It's never going to be enough. We'll always need more!

With USB 3.2, those speeds are going to double. That's right, the new USB 3.2 technology will double the transfer speeds to a whopping 20 gigabits per second. How does it do that? The existing USB 3.1 can transfer data at up to 10 gigabits per second using two lanes (5Gbps per lane), but the new USB 3.2 tech aims to double that to 20Gbps, or 2GB/sec, by allowing for 10Gbps per lane. But of course, you will need to upgrade your hardware first in order to be able to use USB 3.2 in all its glory. There's apparently a lot of focus on the USB-C connectors this time around.

However, the transfer speed is not set in stone. The USB-IF, or the USB Implementers Forum, has not finalised on 20 Gbps yet. Let's hope that they do agree on this real soon. We already know that its going to be a while until this reaches devices that we use everyday.

Gold nanomesh conductor

The world of medical health sensors has thus far, for the most part, been occupied by electronics which are embedded into a material, mostly plastic, which is then stuck onto our bodies. But having some big bulky box attached to your body has its drawbacks, even if it is meant to monitor your health and potentially save your life.

But that might not be the case in the future. A paper was published in the Nature Nanotechnology journal where scientists have created a wearable which looks somewhat like a tattoo. A golden tattoo. The wearable is applied on the skin with a special material called polyvinyl alcohol. This is the same material used to make contact lenses. This material dissolves under water, and leaves only the electric part behind, directly on the skin.

This kind of tech is a step forward for not just medical monitoring, but also remote controlling your gadgets, and maybe even attaching electronics to your own arms.

The only drawback in the tests seems to be that it's not very durable. But hey, no big boxes or straps need to be attached to your bodies. We'll take it.
