RGB V/S NO-RGB

In an effort to see if the addition of RGB affected the quality of the other components of a device, we went about checking the prices of RGB versus non-RGB devices. We looked at case fans and found that the pricing is the same for fans regardless of having RGB or not. It's not like the fan bearings or plastic would be different between these SKUs.

Now, there'd be a couple of you who'd jump and point out that Thermaltake's Riing fans are very expensive. That's where I'd like to point out that Thermaltake's Riing fans incorporate 12 RGB LEDs which can be individually controlled as they showcased this year at Computex

Thermaltake 12 Riing RGB Fan

2017. Which is why they need the custom 9-pin connector for each fan along with a USB header. Now that's not a miniscule feature to be simply disregarded as the RGB implementation that everyone else has managed. Simply put, it's an outlier case.

CRAPPY RGB

Another aspect that drags the argument back onto the table is what many have observed. That RGB products tend to give up much earlier than other components. There's a simple logical bias here. RGB being the attention grabbing mechanism that it is, any fault with it instantly stands out. Take for example, the electrolytic capacitors on motherboards versus the RGB SMT LEDs. The LEDs have an average lifespan of 50,000 hours based on L70. L70 is simply a standard which requires the LED to retain 70% of its lumens over the calculated time period. Electrolytic capacitors on the other hand are rated for 10,000 hours.

However, you're more likely to notice an LED slowly fade away rather than notice the capacitor's gradual failure. So, in your mind you tend to believe that LEDs fail faster than other components.

YAY OR NAY?

We believe that RGB is simply a matter of choice. And we've always been pro-choice. Almost every RGB enabled device can have the lighting aspect turned off. It's much better that you have access to a feature and keep it turned off rather than not have access to it at all. It's absolutely

AVERAGE COMPONENT LIFETIME

Component	Rated Lifetime
PI Device	>>>100,000 hours
LED Based on L70	50,000 hours
Other Semiconductors	>>100,000 hours
Electrolytic Capacitors	~10,000 hours (~1 year)
Ceramic Capacitors	Not defined by manufacturers

obvious that if you lack a sense of taste, then your PC is going to look like a shady opium den from the '70s. However, if you pick and choose carefully and then put some effort into customising your LED setup, then we're certain that you could easily pull off a visual masterpiece. Specially given that most component manufacturers now have a system of synchronising the LEDs with other components within the PC.
