

WT2

Funding: \$151,376 of \$50,000 goal as of writing

Link: <http://dgit.in/kswt2>

WT2 is a wearable that works as a real-time translator. The WT2 kit includes two earphones, an app, and a charging case.

WT2 uses what they call "1+2" technology. What this supposedly allows the WT2 to do is allow "multiplexed (combination of multiple digital and/or analog signals) speech communication between both WT2 earphone translators and a single phone with the WT2 App.

All you need to do to "break down language barriers across the globe" is to pass them an earphone and start talking. It's that easy. You don't have to ask them to download an app on their phone or do anything else.

The most common translators are apps which needs each person involved in the conversation to speak into the phone while the app is running. This requires you to pass the phone around. The other is the 1+1 model with a single phone and earphone. Here you wear the earphone while they speak into the phone speaker or vice versa. The 2+2 model requires two phones with the apps downloaded on both of them. The 1+2 model bypasses all these problems. Definitely a handy translator for travelling enthusiasts. Check WT2 out on Kickstarter.

Pimax

Funding: \$1,488,972 of \$200,000 goal as of writing

Link: <http://dgit.in/kspimax>

The Pimax is a 8K VR headset that's been designed with DIY enthusiasts in mind. The design is intended to be modular, so that it not only works with current tech but can also be further implemented and added onto newer tech in the future. There's room to add features like hand-motion, inside-out tracking, wireless, eye-tracking and more as they come along.

The Pimax comes with a 200 degree FOV or Field of View. This is already more than what both the mainstream VR headsets currently dominating the market are offering. It's also just 20 degrees less than 220 degrees which is the natural FOV for humans.

The design supposedly allows little to no outside light to enter. They've supposedly addressed one of the major drawbacks of VR headsets known as the "Screen door effect". Basically, this is a phenomenon where the eyes are able to distinguish the fine lines between pixels. It's not a very immersive experience. That's a big plus, and one of the biggest complaints people have with VR headsets. But we'll reserve confirmation for after we try it out, if we get to try it out that is.

Let's not forget that you're getting a wide viewing angle WITH 8K resolution. The 8K comes from having 2x 3840x2160 lenses. They also claim to have supposedly dealt with the motion sickness issue. You can find the Pimax 8K headset on Kickstarter starting at \$499.

EOZ Air

Funding: \$169,369 of \$40,000 goal as of writing

Link: <http://dgit.in/kseoz>

EOZ Audio call the EOZ Air the "world's most advanced true wireless earphones". EOZ Air promises the best audio-experience wireless earphones can provide, on par with any major brands out there. They characterise their audio quality by powerful bass, and clear and crispy mid-highs. The earphones house 8mm electro-dynamic drivers and the latest aptX technology. This supposedly reduces the bit rate signifi-

cantly without compromising audio quality. EOZ Air comes with Bluetooth 5.0 support. Of course, that's backwards compatible with older versions of Bluetooth as well. EOZ automatically pairs with the last device

it was used with when removed from its case and will work with any Bluetooth compatible device.

EOZ Air provides four hours of play-time on a single charge with up to 48 hours more with the charging case on the move. EOZ Air is designed to stay in your ears no matter what activity you're doing. It comes with three pairs both memory foam tips and silicone ear tips in different sizes (S, M and L). It's also sweat resistant.

The charging case can be charged via a USB Type-C cable which comes along with the EOZ Air. EOZ Air is live on Kickstarter right now and you can pick a pair up for \$99.
