Rules of Fiction?

Why do so many flicks not stick to the rules that they make up themselves?

Prithvi Sudhan | feedback@digit.in

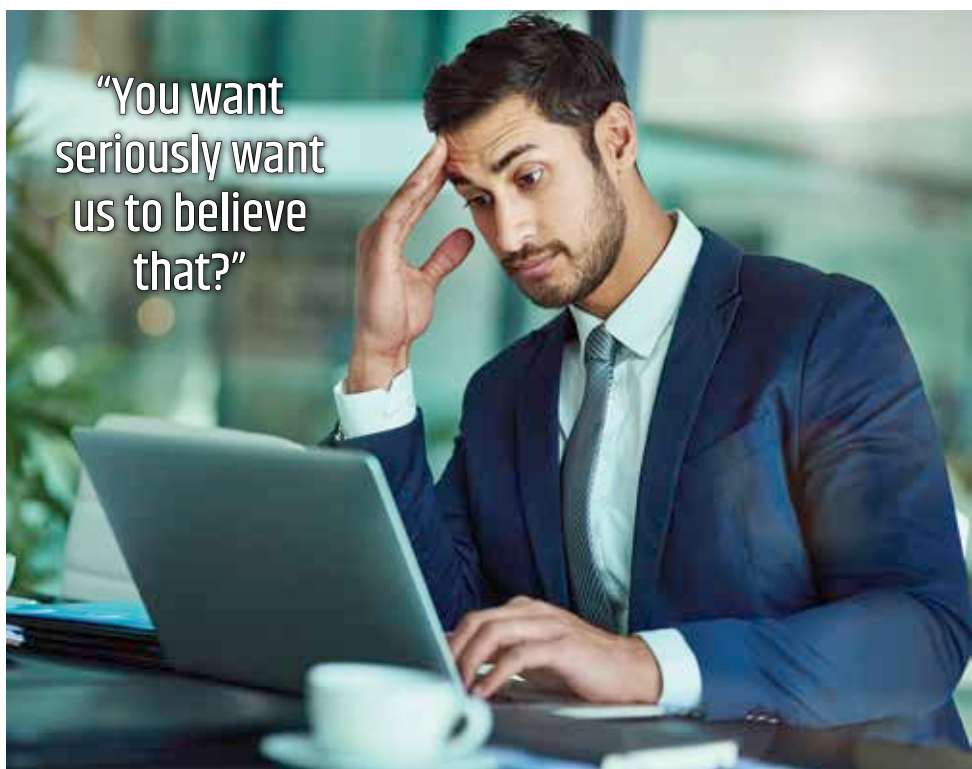

What's the first requirement for watching a superhero movie? Tubs of popcorn and jugs of coke, obviously. What's the second? Leaving your commonsense at the door. At least, partially.

For example, the idea of a radioactive spider biting you and giving you superpowers is a bit preposterous, but we choose to roll with it for the sake of entertainment. However, since not all superheroes (and by extension, their fictional universes) are created equal, some make it easy to suspend logic, while others make you believe the director was on drugs during filming! So let's look at a few examples of what we mean...

FLOUTING THE LAWS OF PHYSICS

This is one the easiest things to overlook, as most superpowers basically fly in the face of physics. However, the one thing that's just too far fetched is Ant-Man. Sure, Pym particles are great and all that, but there hasn't been an accurate description of what they can actually do. There was some pathetic attempt at an explanation that spoke about knocking out the empty space between atoms and all that, but that still doesn't explain how Ant-Man can shrink to *smaller* than an atom!

How is he able to ride Hawkeye's arrow when he's tiny? A man-sized weight on an arrow would now work, and probably break the bow! In the

scene where he falls from a window on to a car, he leaves a 3-inch dent, so if he's heavy, he can't ride arrows, and if he's light, he can't leave such large dents when he falls. Make up your mind Marvel!

And since Balance must exist, we shall now take a look at DC aka the highly physics related superpower that coincidentally ALSO breaks the laws of physics— using the Speedforce. The Flash, technically, is the strongest character ever imagined. Over 9000 levels of OP doesn't even cut it. Let's start with the simplest one. The second most famous physics equation in the world is $F=ma$, i.e. force equals mass times acceleration. And the Flash being, well, the Flash, can accelerate quite a fair bit. Which in turn means that he can pretty much obliterate anything or anyone with just a single punch. And then building up on the acceleration thing, you can literally manipulate time. Make a mistake? No

problem, just go back and fix it again and again until it works out. Added to super speed thinking and you can do some pretty great things, like save everyone in a collapsing building, before it finishes falling down and then go to a library and study all the important bits of construction, go source materials and finish rebuilding the building all in a couple of minutes. We aren't even going to make comments on the speed that's required for such a feat but safe to say there are plenty of illogical zeroes in that number.

Even a miniscule weight on the arrowhead can wreck Hawkeye with the trajectory
