Conversation

This is the UI of your app and defines how users interact with your app after it's invoked by Actions on Google. This is further simplified with the use of a platform known as Dialogflow.

Dialogflow is a framework that allows you to quickly prototype and design the flow of conversations for your app with built-in machine learning and natural language understanding, so you don't have to define an exhaustive grammar. You can also define how to pick up parameters from the user's input in Dialogflow, making it even easier to understand what the user said. Once you build your conversation in Dialogflow, you then define how the app responds to the user in a segment called Fulfillment.

Fulfillment

While Dialogflow handles much of the heavy lifting of understanding natural language and parsing the data you need from user input, the conversation with the user will probably require the app to perform some business logic to respond to the user and to complete the task. To do this a web service (called fulfillment) is called. This web service is designed by implementing the Dialogflow webhook, which is a JSON-based protocol that defines a schema for interacting with Google Assistant from an external service.

When users say something, the app receives some text and a set of parameters from that data. Then it uses this data to return a response to move the conversation ahead.

DESIGN AN APP

In the following segments we will attempt to design our own app for the Google Assistant platform. In the spirit of the new year, let us try to keep things light and try to design an application that tells you your fortune in a comic manner. To start off, we should come up with a set of sample conversations to get an idea of how we want our app to look. Thankfully, as we said, prototyping on Dialogflow is pretty easy.

HAPPY PATH

App: Hi! Welcome to FortuneGuru! Let's get started. What is your birth date?

User: December

App: What is your favorite color?

User: Yellow

App: Now would be a good time to take up a new sport!

USER PROVIDES BAD INPUT

App: Hi! Welcome to FortuneGuru! Let's get started. What is your birth date?

User: Apricot

App: Hmm that doesn't sound like a date to me. Will you tell me what's your birth date again?

User: June

App: What is your favorite color?

User: Blue

App: Your resemblance to a muppet will prevent the world from taking you seriously!

Create an Actions project and Dialogflow agent

To develop for Actions on Google, you need to create an Actions project and Dialogflow agent. The Actions project lets you register your actions, manage your app through the approval process, view analytics for your app, and more. The Dialogflow agent defines what users can say to your app and how your app processes user input.

Creating an Actions Project

- Open the Google Developer Console > navigate to **Actions on Google**.
- Click on **Add Project**, enter FortuneGuru for the project name, and click Create Project.
- In the Dialogflow flashcard, click on the **BUILD** button and then **Create Actions On Dialogflow** to start building actions.
- On the next screen, you see the Dialogflow console with information automatically populated in an agent. Click **Create** to save the demo agent.

- Your agent will eventually call some fulfillment logic that you'll build later to return a response with the user's fortune, but for now let's keep a dummy fulfillment.
- Click the Fulfillment menu item and then move the disabled slider for Webhook to the right to 'Enabled'. Enter a dummy URL for now, like <https://fortune.guru.fulfillment>. We'll update this URL when our actual fulfillment service is ready. Finally click **Save**.

Define actions and invocation

- When creating a Dialogflow agent a default intent is automatically created. This intent represents the main entry to your conversation app. All your apps must have at least this main action defined, so that Actions on Google knows how to invoke your app. The intent has an action field that specifies an action name. When an intent is triggered, this is sent to your fulfillment so it can map the action's name to the task to carry out.
- For the default Welcome Intent, delete the pre-populated responses in the Text response fields by clicking on the trash can icon in the upper-right corner. Click on **ADD MESSAGE CONTENT** > **Text response**, specify the following response instead, and click **Save**.
"Hi! Welcome to FortuneGuru! Let's get started. What is your birth date?"
- Now, when users invoke your app, they face the above welcome message and can now experience your app. In general, responses should guide users on what to say next and to stay within your conversation grammar.

Define your conversation grammar

- A group of Dialogflow intents collectively constitute your app's conversation grammar and what tasks to carry out when users speak particular phrases of your grammar. As Dialogflow already pre-packages a natural language understanding (NLU) engine, it au-
