

Wi-Fiber Intelli-Platform Integrated Streetlights

Connected streetlights that feature cameras, IoT, local Wi-Fi and lights that can change colour for various purposes

One of the biggest problems that cutting edge technology faces is that it is really expensive to replace existing infrastructure with it. Hence, any technology that also removes the need for a total replacement and simply augments existing stuff into being able to do cutting edge work, that is bound to receive a lot of attention and that is exactly what happened with Wi-Fiber Intelli-Platform Integrated Streetlights at CES 2018. An entire modular street lamp setup can be customised to provide smart lighting to municipal Wi-Fi. The system can be fitted out with a host of other add-ons like a 4K camera, two-way microphone and speaker system, gunshot sensors, air-quality monitors and more. The LED lights could change colour to direct law-enforcement or healthcare authorities to the right locations. Best part, it can be installed onto existing streetlamps in under 30 minutes.

Lishtot's TestDrop

Device to check the quality of drinking water

Lishtot Testdrop is a device that wants to solve the world's drinking water problem by providing an easy way to detect if water is safe to drink – without even touching the water itself. Testdrop works by analysing the electric field around water and indicates the safety of the same by showing a blue or red light for safe or unsafe water respectively. Every object emits an electromagnetic field, and Testdrop can tell the difference between clean

water and water with E.coli, lead, chlorine or other risky contaminants. It requires

the water to be placed in a plastic

cup, because plastic doesn't interfere with the field, but it can work for several years on a single watch battery, even when used 10-20 times per day! You can also pair it with an app to record readings in a database to help authorities determine water quality across the world. The device costs a mere \$50.

Nomadic Audio Speakase

A suitcase that doubles up as high performance speakers

Another winner of several CES 2018 Innovation awards was the Nomadic Audio Speakase. Yes, that does sound like a weird name for a reason. The Speakase combines a good bluetooth speaker with a suitcase to provide high quality, powerful sound – anywhere, anytime. The speaker itself is well made, with adjustable bass and treble dials and a water-resistant material. Let the name not fool you, the package does contain a bluetooth speaker that can be used independently as well. But putting it behind the speaker grills in the Speakase and locking it in is where the truly big sound emerges. The suitcase is built to match the quality standards of premium suitcases, having a polycarbonate body with an aluminum reinforced frame. It also packs in shock absorbers to keep the speakers, as well as the case, safe while travelling. Now you know what to take on your next camping trip!

Xenoma

Clothing to detect body movements and stress levels

Smart clothing has a lot of potential if done right. From completely getting rid of controllers in games to actually removing the need for hefty monitoring equipment in hospitals, connected clothing can work wonders. And that's what Xenoma has shown the potential for this year at CES 2018. While their original prototype debuted last year, this year they brought a more advanced version of their smart shirt that packs in 14 sensors that can detect

all kinds of motion and stats on your body. The company's E-skin technology doesn't require a gel to be placed between the sensors and the skin, and the clothes they've built can be washed as much as regular clothes without losing durability. Xenoma's lineup could potentially be able to link to VR headsets or to medical equipment as well.
