

Monkeys have been cloned

Chinese scientists have successfully cloned two monkeys, but they have no intention of cloning humans yet. <http://digit.in/MnkyCline>

Predicting psychos

A big data speech analysis software has managed to predict psychosis in at-risk patients with up to 83% accuracy. <http://digit.in/BdataPsy>

KEPLER-186 F

Kepler-186 f was the first Earth-sized exoplanet to be found in the habitable zone of its host star. The world is only about ten percent larger than the Earth, but its composition and mass are not yet known. The planet receives only about a third of the energy as the Earth receives from the Sun. For an observer on the surface at noon, the star would appear about as bright as the Sun on Earth just before sunset. There are four other planets in the system, which are too close to the host star to support life. Kepler-186 is about 550 light years away and appears in the constellation of Cygnus.

KEPLER-442 B

This planet is very similar to the Earth, and right in the middle of the habitable zone of the host star. The host star is an orange dwarf, which means that there is plenty of energy for life to emerge and thrive on this system. However, early in their life, orange dwarf stars bombard the planets with an excessive amount of ultraviolet radiation. Currently the planet basks in moderate warmth, receiving about 70 percent of the light that Earth receives from the Sun. The planet takes a trip around the host star about once every 112 days. This star is 1,120 light years away and appears in the constellation of Lyra.

KEPLER-1229 B

Kepler-1229 b is larger than the Earth, and orbits at the outer edge of the habitable zone of its host star, going around Kepler-1229 once every 86.8 Earth days. The host star is an orange dwarf, which stays stable for 15 to 30 billion years, as against the 10 billion years of our Sun. Planets in orbit around such stars are promising candidates for the search for extraterrestrial life. Unfortunately, the star is too far for even the next generation of space telescopes to check for an atmosphere or signs of life. The host star is 770 light years away and appears in the constellation of Cygnus.

KEPLER-62 F

Kepler-62f is a super Earth about 40 percent larger than the Earth. The composition and mass of the planet is however, not yet known. The planet is the outermost one in a system containing at least five other planets. Kepler-62 is an orange dwarf star, cooler and smaller than the Sun. The planet receives about 41 percent of the light that Earth receives from the Sun. The system is pretty ancient as the star is more than seven billion years old. The planet is right in the heart of the habitable zone around the star. The star is pretty distant, at 1,200 light years away in the constellation of Lyra.
