

A zoomed in view of the plate showcasing the tunnel created. The electrons strike the surface of these tunnels which generates more electrons which are passed on to the phosphor screen.

Phosphor screen

The phosphor screen converts the striking electrons to photons i.e. back to light, which is transmitted to the image intensifier. Colour green is chosen as the human eye is most sensitive to it.

5

Exit visibility

The image intensifier highlights the green image received from the phosphor screen and adds more detail. The image looks clearer at this stage. The final night vision image is then passed along to the eye-piece.
